## Affected Environment (EA) the 2012-2013 Skate Specification Package

## Section 7.2 Description of the Biological Environment

Section 7.5.1 Description of the Fishery
Section 7.5.4.2 Skate Prices
2010

Prepared by the
New England Fishery Management Council in consultation with National Marine Fisheries Service

June 2010

### 1.0 Table of Contents

### 7.0 DESCRIPTION OF THE RESOURCE AND THE AFFECTED ENVIRONMENT (EIS) (SAFE REPORT); SOCIO-ECONOMIC ENVIRONMENT AND FISHERY IMPACT STATEMENT. 7-1

1.0 Table of Contents .....................................................................................................................7-4
1.1 List of Tables .......................................................................................................................7-6
1.2 List of Figures ....................................................................................................................7-11
1.3 List of Maps ........................................................................................................................7-12
7.0 SAFE Report..........................................................................................................................7-14
7.1 Introduction........................................................................................................................7-14
7.2 Biological Environment......................................................................................................7-16
7.2.1 Species Distribution ......................................................................................................7-16
7.2.2 Stock assessment and status (SAW 44)..........................................................................7-16
7.2.3 Research Survey Data ...................................................................................................7-17
7.2.3.1 Winter Skate ........................................................................................................7-18
7.2.3.2 Little Skate...........................................................................................................7-26
7.2.3.3 Barndoor Skate ....................................................................................................7-32
7.2.3.4 Thorny Skate ........................................................................................................7-38
7.2.3.5 Smooth Skate........................................................................................................7-44
7.2.3.6 Clearnose Skate ....................................................................................................7-49
7.2.3.7 Rosette Skate ........................................................................................................7-55
7.2.4 Life History Characteristics and Biological Reference Points .........................................7-61
7.2.4.1 Winter Skate .........................................................................................................7-61
7.2.4.2 Little Skate............................................................................................................7-62
7.2.4.3 Barndoor Skate ......................................................................................................7-63
7.2.4.4 Thorny Skate .......................................................................................................7-64
7.2.4.5 Smooth Skate........................................................................................................7-65
7.2.4.6 Clearnose Skate ....................................................................................................7-65
7.2.4.7 Rosette Skate ........................................................................................................7-66
7.2.5 Feeding habits ...............................................................................................................7-66
7.2.5.1 Winter Skate .........................................................................................................7-71
7.2.5.2 Little Skate...........................................................................................................7-71
7.2.5.3 Barndoor Skate .....................................................................................................7-71
7.2.5.4 Thorny Skate ........................................................................................................7-71
7.2.5.5 Smooth Skate........................................................................................................7-72
7.2.5.6 Clearnose Skate .....................................................................................................7-72
7.2.5.7 Rosette Skate .........................................................................................................7-72
7.2.6 Evaluation of Fishing Mortality and Stock Abundance ...................................................7-72
7.2.6.1 Winter Skate ........................................................................................................7-73
7.2.6.2 Little Skate............................................................................................................7-74
7.2.6.3 Barndoor Skate ......................................................................................................7-74
7.2.6.4 Thorny Skate ........................................................................................................7-74
7.2.6.5 Smooth Skate........................................................................................................7-75
7.2.6.6 Clearnose Skate ....................................................................................................7-75
7.2.6.7 Rosette Skate .........................................................................................................7-75
7.2.6.8 SARC Comments ..................................................................................................7-76
7.2.7 Marine Mammals and Protected Species ..... 7-77
7.2.7.1 $\quad$ Sea Turtles ..... 7-78
7.2.7.2 Large Cetaceans (Baleen Whales and Sperm Whale) ..... 7-78
7.2.7.3 Small Cetaceans (Dolphins, Harbor Porpoise and Pilot Whale) ..... 7-79
7.2.7.4 Pinnipeds ..... 7-80
7.3 Physical Environment ..... 7-80
7.3.1 Gulf of Maine ..... 7-81
7.3.1.1 Physical Environment ..... 7-81
7.3.1.2 Benthic Invertebrates ..... 7-86
7.3.1.3 Demersal Fish ..... 7-87
7.3.2 Georges Bank ..... 7-90
7.3.2.1 Physical Environment ..... 7-90
7.3.2.2 Invertebrates ..... 7-92
7.3.2.3 Demersal Fish ..... 7-93
7.3.3 Mid-Atlantic Bight ..... 7-93
7.3.3.1 Physical Environment ..... 7-93
7.3.3.2 Invertebrates ..... 7-97
7.3.3.3 Demersal Fish ..... 7-97
7.3.4 Continental Slope ..... 7-103
7.3.4.1 Physical Environment ..... 7-103
7.3.4.2 Invertebrates ..... 7-107
7.3.4.3 Demersal Fish ..... 7-107
7.4 Essential Fish Habitat ..... 7-110
7.4.1 Habitat Effects of Fishing ..... 7-117
7.4.2 Otter Trawls - Mud ..... 7-119
7.4.2.1 Physical Effects ..... 7-119
7.4.2.2 Biological Effects ..... 7-120
7.4.3 Otter Trawls - Sand ..... 7-120
7.4.3.1 Physical effects ..... 7-121
7.4.3.2 Biological effects ..... 7-121
7.4.4 Otter Trawls - Gravel/Rocky Substrate ..... 7-122
7.4.4.1 Physical effects ..... 7-122
7.4.4.2 Biological effects ..... 7-122
7.4.5 Otter Trawls - Mixed Substrates ..... 7-122
7.4.5.1 Physical effects ..... 7-123
7.4.5.2 Biological effects ..... 7-123
7.4.6 New Bedford Scallop Dredges - Sand ..... 7-123
7.4.6.1 Physical effects ..... 7-123
7.4.6.2 Biological effects ..... 7-123
7.4.7 New Bedford Scallop Dredges - Mixed Substrates ..... 7-124
7.4.7.1 Physical effects ..... 7-124
7.4.8 Hydraulic Clam Dredges - Sand ..... 7-124
7.4.8.1 Physical effects ..... 7-124
7.4.8.2 Biological effects ..... 7-125
7.4.9 Hydraulic Clam Dredges - Mixed Substrates. ..... 7-125
7.5 Economic Environment. ..... 7-126
7.5.1 Description of Directed Skate Fisheries ..... 7-126
7.5.1.1 The Skate Bait Fishery ..... 7-126
7.5.1.1.1 Rhode Island Bait Fishery ..... 7-126
7.5.1.1.2 Other Bait Fishery Ports ..... 7-128
7.5.1.1.3 The Southern New England Sink Gillnet Fishery ..... 7-128
7.5.1.1.4 Regulatory Issues for the Bait Fishery ..... 7-128
7.5.1.2 The Skate Wing Fishery ..... 7-129
7.5.1.3 Commercial Fishery Landings. ..... 7-130
7.5.1.3.1 Total Commercial Landings ..... 7-130
7.5.1.3.2 Landings by fishery ..... 7-131
7.5.1.3.3 Landings by State ..... 7-133
7.5.1.3.4 Landings by Market Category ..... 7-134
7.5.1.3.5 Landings by Gear ..... 7-137
7.5.1.3.6 Landings by port ..... 7-138
7.5.1.3.7 Landings by Day-at-Sea Program (to be updated) ..... 7-140
7.5.1.4 Fishing Areas ..... 7-143
7.5.1.5 Canadian skate landings ..... 7-146
7.5.1.6 Recreational skate catches ..... 7-149
7.5.1.7 Discards ..... 7-151
7.5.2 Description of the Skate Processing Sector (???needs updating???) ..... 7-158
7.5.3 Domestic and International Markets for Skates ..... 7-158
7.5.4 Economic information ..... 7-159
7.5.4.1 Economic Framework ..... 7-159
7.5.4.2 Dockside Prices for Skates (???needs updating???) ..... 7-160
7.5.4.3 Price Models ..... 7-165
7.5.4.4 Revenues from Skate Landings ..... 7-165
7.5.5 Skate Vessels ..... 7-169
7.5.5.1 Skate Dealers ..... 7-173
7.5.5.2 Processors ..... 7-174
7.5.5.3 International Trade ..... 7-174
7.6 Social Environment ..... 7-175
7.6.1 Vessels by Homeport and Owner's Residence ..... 7-175
7.6.2 Other Permits Held by Skate Permit Holders ..... 7-177
7.6.3 Commercial Ports of Landing ..... 7-177
7.6.4 Census Data for Top Skate Ports ..... 7-181
7.6.5 Skate Dealers ..... 7-183
7.6.6 Skate Processors ..... 7-185
7.6.7 Skate Fishing Areas ..... 7-186
7.6.8 Data on Lobster Fishing in Top Skate Ports ..... 7-187
7.7 Glossary of Terms and Acronyms ..... 7-189
7.8 SAFE Report/Affected Environment References ..... 7-195

### 1.1 List of Tables

Table 1. Skate Species Identification for Northeast Complex
Table 2. Summary by species of recent survey indices, survey strata used and biomass reference points.719
Table 3. Abundance and biomass from NEFSC spring surveys for winter skate for the Gulf of Maine to Mid-Atlantic region (offshore strata 1-30,33-40,61-76). The mean index, $95 \%$ confidence intervals, individual fish weight, minimum, mean, and maximum length, 5th, 50th, and 95th percentiles of length, number of nonzero tows, and number of fish caught are presented for 20002006.

Table 4. Abundance and biomass from NEFSC autumn surveys for winter skate for the Gulf of Maine to Mid-Atlantic region (offshore strata 1-30, 33-40, 61-76). The mean index, $95 \%$ confidence intervals, individual fish weight, minimum, mean, and maximum length, 5th, 50th, and 95th percentiles of length, number of nonzero tows, and number of fish caught are presented for 20002005. ..........................................................................................................................................7-22

Table 5. Abundance and biomass from NEFSC winter surveys for winter skate for the Georges Bank to Mid-Atlantic region (offshore strata 1-3,5-7,9-11,13-14,16,61-63,65-67,69-71,73-75). The mean index, $95 \%$ confidence intervals, individual fish weight, minimum, mean, and maximum length, 5th, 50th, and 95 th percentiles of length, number of nonzero tows, and number of fish caught are presented for 2000-2006. Stratum 16 not sampled in 1993, 2000, 2002-2006. Strata 13 and 14 not sampled in 2003. Stratum 63 not sampled in 1993. Stratum 14 not sampled in 2005........7-23

Table 6. Abundance and biomass from NEFSC spring surveys for little skate for the Gulf of Maine to Mid-Atlantic region (offshore strata 1-30, 33-40, 61-76, and inshore strata 1-66). The mean index, $95 \%$ confidence intervals, individual fish weight, minimum, mean, and maximum length, 5 th, 50th, and 95th percentiles of length, number of nonzero tows, and number of fish caught are presented for 2000-2006. 7-28

Table 7. Abundance and biomass from NEFSC autumn surveys for little skate for the Gulf of Maine to Mid-Atlantic region (offshore strata 1-30,33-40,61-76, and inshore strata 1-66). The mean index, $95 \%$ confidence intervals, individual fish weight, minimum, mean, and maximum length, 5 th, 50th, and 95th percentiles of length, number of nonzero tows, and number of fish caught are presented for 2000-2005.

7-28
Table 8. Abundance and biomass from NEFSC winter surveys for little skate for the Georges Bank to Mid-Atlantic region (offshore strata 1-3,5-7,9-11,13-14,16,61-63,65-67,69-71,73-75). The mean index, $95 \%$ confidence intervals, individual fish weight, minimum, mean, and maximum length, 5 th, 50 th, and 95 th percentiles of length, number of nonzero tows, and number of fish caught are presented for 2000-2006. Stratum 16 not sampled in 1993, 2000, 2002-2006. Strata 13 and 14 not sampled in 2003. Stratum 63 not sampled in 1993. Stratum 14 not sampled in 2005. 7-29

Table 9. Abundance and biomass from NEFSC spring surveys for barndoor skate for the Gulf of Maine to Southern New England region (offshore strata 1-30, 33-40). The mean index, $95 \%$ confidence intervals, individual fish weight, minimum, mean, and maximum length, 5th, 50th, and 95th percentiles of length, number of nonzero tows, and number of fish caught are presented for 20002006.

7-34
Table 10. Abundance and biomass from NEFSC autumn surveys for barndoor skate for the Gulf of Maine to Southern New England region (offshore strata 1-30, 33-40). The mean index, 95\% confidence intervals, individual fish weight, minimum, mean, and maximum length, 5th, 50th, and 95 th percentiles of length, number of nonzero tows, and number of fish caught are presented for 2000-2005. 7-34

Table 11. Abundance and biomass from NEFSC winter surveys for barndoor skate for the Georges Bank to Mid-Atlantic region (offshore strata 1-3,5-7,9-11,13-14,16,61-63,65-67,69-71,73-75). The mean index, $95 \%$ confidence intervals, individual fish weight, minimum, mean, and maximum length, 5 th, 50 th, and 95 th percentiles of length, number of nonzero tows, and number of fish caught are presented for 2000-2006. Stratum 16 not sampled in 1993, 2000, 2002-2006. Strata 13 and 14 not sampled in 2003. Stratum 63 not sampled in 1993. Stratum 14 not sampled in 2005. 7-35

Table 12. Abundance and biomass from NEFSC spring surveys for thorny skate for the Gulf of Maine to Southern New England region (offshore strata 1-30, 33-40). The mean index, $95 \%$ confidence intervals, individual fish weight, minimum, mean, and maximum length, 5th, 50th, and 95th
percentiles of length, number of nonzero tows, and number of fish caught are presented for 20002006
Table 13. Abundance and biomass from NEFSC autumn surveys for thorny skate for the Gulf of Maine to Southern New England region (offshore strata 1-30, 33-40). The mean index, $95 \%$ confidence intervals, individual fish weight, minimum, mean, and maximum length, 5th, 50th, and 95th percentiles of length, number of nonzero tows, and number of fish caught are presented for 20002005

Table 14. Abundance and biomass from NEFSC spring surveys for smooth skate for the Gulf of Maine to Southern New England region (offshore strata 1-30, 33-40). The mean index, $95 \%$ confidence intervals, individual fish weight, minimum, mean, and maximum length, 5th, 50th, and 95th percentiles of length, number of nonzero tows, and number of fish caught are presented for 20002006. 7-46
Table 15. Abundance and biomass from NEFSC autumn surveys for smooth skate for the Gulf of Maine to Southern New England region (offshore strata 1-30, 33-40). The mean index, $95 \%$ confidence intervals, individual fish weight, minimum, mean, and maximum length, 5th, 50th, and 95th percentiles of length, number of nonzero tows, and number of fish caught are presented for 20002005. 7-46
Table 16. Abundance and biomass from NEFSC spring surveys for clearnose skate for the Mid-Atlantic region (offshore strata 61-76, inshore strata 15-44). The mean index, $95 \%$ confidence intervals, individual fish weight, minimum, mean, and maximum length, 5th, 50th, and 95th percentiles of length, number of nonzero tows, and number of fish caught are presented for 2000-2006.

Table 17. Abundance and biomass from NEFSC autumn surveys for clearnose skate for the Mid-Atlantic region (offshore strata 61-76, inshore strata 15-44). The mean index, $95 \%$ confidence intervals, individual fish weight, minimum, mean, and maximum length, 5 th, 50 th, and 95 th percentiles of length, number of nonzero tows, and number of fish caught are presented for 2000-2005. 7-51

Table 18. Abundance and biomass from NEFSC winter surveys for clearnose skate for the Georges Bank to Mid-Atlantic region (offshore strata 1-3,5-7,9-11,13-14,16,61-63,65-67,69-71,73-75). The mean index, $95 \%$ confidence intervals, individual fish weight, minimum, mean, and maximum length, 5 th, 50 th, and 95 th percentiles of length, number of nonzero tows, and number of fish caught are presented for 2000-2006. Stratum 16 not sampled in 1993, 2000, 2002-2006. Strata 13 and 14 not sampled in 2003. Stratum 63 not sampled in 1993. Stratum 14 not sampled in 2005.

7-52
Table 19. Abundance and biomass from NEFSC spring surveys for rosette skate for the Mid-Atlantic region (offshore strata 61-76). The mean index, $95 \%$ confidence intervals, individual fish weight, minimum, mean, and maximum length, 5th, 50th, and 95 th percentiles of length, number of nonzero tows, and number of fish caught are presented for 2000-2006.
Table 20. Abundance and biomass from NEFSC autumn surveys for rosette skate for the Mid-Atlantic region (offshore strata 61-76). The mean index, $95 \%$ confidence intervals, individual fish weight, minimum, mean, and maximum length, 5th, 50th, and 95 th percentiles of length, number of nonzero tows, and number of fish caught are presented for 2000-2005.
Table 21. Abundance and biomass from NEFSC winter surveys for rosette skate for the Georges Bank to Mid-Atlantic region (offshore strata 1-3,5-7,9-11,13-14,16,61-63,65-67,69-71,73-75). The mean index, $95 \%$ confidence intervals, individual fish weight, minimum, mean, and maximum length, 5th, 50 th, and 95 th percentiles of length, number of nonzero tows, and number of fish caught are presented for 2000-2006. Stratum 16 not sampled in 1993, 2000, 2002-2006. Strata 13 and 14 not sampled in 2003. Stratum 63 not sampled in 1993. Stratum 14 not sampled in 2005. 7-58

### 7.0 SAFE Report

### 7.1 Introduction

This document serves two purposes: an update of the Stock Assessment and Fishery Evaluation Report (SAFE) and a Description of the Affected Environment (Section 7) for the Environmental Assessment (EA) for the 2012-2013. Since the document serves as Section 7 of the EA in Amendment 3, it is numbered beginning with Section 7 in this stand-alone SAFE Report to reduce confusion. There is therefore no Sections 1-6 in the stand-alone SAFE Report.

This section is intended to provide background information for assessing the impacts, to the extent possible, of the proposed management measures on related physical, biological, and human environments. It includes a description of the stocks and the physical environment of the fishery as well as life history information, habitat requirements, and stock assessments for relevant stocks and a discussion of additional biological elements such as endangered species and marine mammals. This descriptive section also describes the human component of the ecosystem, including socioeconomic and cultural aspects of the commercial and recreational fisheries and the impacts of other human activities on the fisheries in question. Much of the information contained in this section is a compilation of information used to make choices from a range of alternatives during the development of the proposed management action.

This Stock Assessment and Fishery Evaluation (SAFE) Report was prepared by the New England Fishery Management Council's Skate Plan Development Team (PDT). It presents available biological, physical, and socioeconomic information for the northeast's region skate complex and its associated fisheries. It also serves as the Affected Environment description for the Environmental Assessment associated with the 2012-2013 specifications package.

Table 1 presents the seven species in the northeast region's skate complex, including each species common name(s), scientific name, size at maturity (total length, TL), and general distribution.

Table 1. Skate Species Identification for Northeast Complex

| SPECIES <br> COMMON <br> NAME | SPECIES <br> SCIENTIFIC <br> NAME | GENERAL <br> DISTRIBUTION | SIZE AT <br> MATURITY cm <br> (TL) | OTHER <br> COMMON <br> NAMES |

### 7.2 Biological Environment

The Essential Fish Habitat Source Documents prepared by the Northeast Fisheries Science Center (NEFSC) of the National Marine Fisheries Service for each of the seven skate species, provide most available biological and habitat information on skates. These technical documents are available at http://www.nefsc.noaa.gov/nefsc/habitat/efh/:

Life history, including a description of the eggs and reproductive habits
Average size, maximum size and size at maturity
Feeding habits
Predators and species associations
Geographical distribution for each life history stage
Habitat characteristics for each life history stage
Status of the stock (in general terms, based on the Massachusetts inshore and NEFSC trawl surveys)
A description of research needs for the stock
Graphical representations of stock abundance from NEFSC trawl survey and Massachusetts inshore trawl survey data
Graphical representations of percent occurrence of prey from NEFSC trawl survey data

### 7.2.1 Species Distribution

Maps of biomass distribution are included in Section 7.2.3, but additional maps of the abundance distribution for juveniles and adults are published in the 2002 SAFE Report
(http://www.nefmc.org/skates/fmp/skate_SAFE.htm).

### 7.2.2 Stock assessment and status (SAW 44)

The Stock Assessment Review Committee (SARC) meeting of the 44th Northeast Regional SAW was held in the Aquarium Conference Room of the Northeast Fisheries Science Center's (NEFSC) Woods Hole Laboratory in Woods Hole, Massachusetts from October $24-26$, 2006. The SARC Chairman was Dr. Paul Rago, Northeast Fisheries Science Center, NOAA, Woods Hole, Massachusetts. Members of the SARC included scientists from the NEFSC, NMFS Northeast Regional Office (NERO), NMFS Headquarters, the Mid-Atlantic Fishery Management Council (MAFMC), Atlantic States Marine Fisheries Commission (ASMFC), the States of Rhode Island and Massachusetts, DFO-Canada, and the Virginia Institute of Marine Sciences. The $44^{\text {th }}$ SAW was held in Woods Hole in December 2007 and
reviewed the SARC results. The SAW rejected the analytic assessment models that were presented by the SARC because they had not been adequately tested using simulated populations. The SAW recommended using the existing status determination criteria for determining whether skates were overfished or whether overfishing had occurred, as a proxy for MSY-based reference points. Preliminary results from SAW 44 were presented to the Council at its February 2007 meeting and the final results were published in May 2007 (http://www.nefsc.noaa.gov/nefsc/saw/).

The following Terms of Reference were provided by the SAW Steering Committee as the context for the assessment of the northeast region skate complex reviewed by SARC 44 in October 2006:

- Characterize the commercial and recreational catch including landings and discards.
- Estimate fishing mortality, spawning stock biomass, and total stock biomass for the current year and characterize the uncertainty of those estimates. If possible, also include estimates for earlier years.
- Either update or redefine biological reference points (BRPs; proxies for $\mathrm{B}_{\text {MSY }}$ and $\mathrm{F}_{\text {MSY }}$ ).
- Evaluate current stock status with respect to the existing BRPs, as well as with respect to updated or redefined BRPs (from TOR 3).
- Review, evaluate and report on the status of the SARC/Working Group Research Recommendations offered in recent SARC-reviewed assessments.
- Examine the NEFSC Food Habits Database to estimate diet composition and annual consumptive demand for seven species of skates for as many years as feasible.

For the purposes of simplification, not all of the information contained in the SAW 44 documents is presented in this SAFE Report. The SAW 44 documents (see http://www.nefsc.noaa.gov/nefsc/saw/) are referenced in this SAFE Report and should be consulted for more information about population stock assessment, long term landings, long term discard estimates, and long term survey trends.

The SARC at SAW 30 developed the following biological reference points for each of the seven species of skates in the northeast complex. Alternative reference points were proposed by the SARC at SAW 44. However, these proposed reference points were rejected, resulting in the previous reference points being retained. An evaluation of each species' status in the context of the following reference points is provided in the following section of this document.

### 7.2.3 Research Survey Data

This section presents data collected through seasonal NEFSC trawl surveys and state research surveys. Information has been updated through the 2005 autumn survey and the 2006 spring survey.

Indices of relative abundance have been developed from NEFSC bottom trawl surveys for the seven species in the skate complex, and these form the basis for most of the conclusions about the status of the complex. All statistically significant NEFSC gear, door, and vessel conversion factors were applied to little, winter, and smooth skate indices when applicable (Sissenwine and Bowman, 1978; NEFSC 1991). For the aggregate skate complex, the spring survey index of biomass exhibited an increase in the late 1990s to early 2000s has recently begun to decline again (http://www.nefsc.noaa.gov/nefsc/publications/crd/crd0710/b.pdf).

The biomass of large-sized skates has steadily declined since the mid-1980s but has remained relatively stable since the late 1990s. An increase in little skate drove the higher abundance of small skates in 1999, but recently the abundance of little skate has declined.

### 7.2.3.1 Winter Skate

NEFSC bottom trawl surveys indicate that winter skate are most abundant in the Georges Bank (GB) and Southern New England (SNE) offshore strata, with few fish caught in the Gulf of Maine (GOM), or MidAtlantic (MA) regions (Map 1).

The median length of winter skates sampled by the survey generally, in both the spring and autumn surveys, increased from the mid 1990s through 2002, and then declined slightly to about $45-52 \mathrm{~cm}$ TL ( $18-20 \mathrm{in}$ ). Length frequency distributions from the NEFSC spring and autumn surveys are presented in the SAW 44 documents and are not reproduced in this SAFE Report. Truncation of the length distributions is evident in the NEFSC spring and autumn series since 1990.

Recent spring survey catches have equated to 3.1 fish or 3.0 kg per tow in 2006; recent autumn catch equates to 1.7 fish or 2.6 kg per tow in 2005 (Table 3 and Table 4). The 2006 stratified mean catch is 18.2 fish per tow or 32.4 kg per tow, the highest index since 1991(Table 5). NEFSC survey indices of winter skate abundance are below the time series mean, at about the same value as during the early 1970s. This downward trend is observed in the fall, spring and summer surveys (Figure 1). Current NEFSC indices of winter skate biomass are about $38 \%$ of the peak observed during the mid 1980 s.

In 2007, winter skate was determined to be overfished, because the biomass index dropped below the threshold. This status remained unchanged in 2008 upon examination of the autumn 2007 survey data. Overfishing is not occurring on this species because the consecutive three-year moving average of the biomass indices did not exceed the maximum threshold which according to the FMP defines when overfishing is occurring.

Table 2. Summary by species of recent survey indices, survey strata used and biomass reference points.

|  | BARNDOOR | CLEARNOSE | LITTLE | ROSETTE | SMOOTH | THORNY | WINTER |

Distribution of winter skate in Canadian waters was examined using research surveys and commercial fishery data by Simon et al. (2003). Winter skate are found from Georges Bank north into the Gulf of St. Lawrence (Simon et al. 2003). Lower concentrations are found on the southern part of the Grand Banks and in nearshore areas of Newfoundland. Research surveys conducted on Georges Bank indicate a higher abundance of winter skate on the USA side of the Bank. No trend in abundance was found in the Georges Bank region; the series average is 1.8 million individuals. In the Gulf of St Lawrence, declines have been evident in the Southern Gulf (decadal averages range from 650,000 individuals in the 1970s, 450,000 individuals in the 1980s, and 170,000 individuals in the 1990s) but have remained stable in the northern area. Since 1998 a noted decline in abundance was observed on the Scotian Shelf; the average from 1998 to 2003 was 1.4 million individuals, which is below the long-term series average of 2.6 million individuals. Frisk et al. (2008) propose that connectivity exists between skate populations, in particular between the Scotian Shelf and Georges Bank. If this connectivity really exists, movement between the two populations would partially explain the increase in winter skate on Georges Bank during the 1980s, if Georges Bank indeed received an influx of winter skates from the Scotian Shelf.

Biological data are limited for this species in Canadian waters. For part of the Scotian Shelf region (NAFO division 4VsW) $50 \%$ maturity was considered to be at 75 cm total length for both sexes (Simon et al. 2003). In Division 4VsW, the number of mature individuals has been declining throughout the time series, with no individuals above 75 cm being caught in 2001 and 2002. Maturity at length estimates are not available for other regions.

In 2005, the Committee on the Status of Endangered Wildlife in Canada (COSEWIC) released a status assessment on winter skate that designated this species to be endangered, threatened, and is of special concern and data deficient, based primarily on its life history characteristics and the low frequency of occurrence in catches (Anonymous, 2005).

Indices of abundance for winter skate are available from the Massachusetts Division of Marine Fisheries (MADMF) spring and autumn research trawl surveys in the inshore waters of Massachusetts during 19782006. The spring survey index rebounded to moderate levels during 1992-1996 before dropping again to low values in the late 1990s and remaining low through 2006 (SAW44 2006). The autumn index is more variable, but generally shows the same pattern. Indices of abundance for winter skate are also available from the Connecticut Department of Environmental Protection (CTDEP) spring and autumn finfish trawl surveys in Long Island Sound during 1984-2006. Annual CTDEP survey catches have ranged from 0 to 115 skates. CTDEP survey indices suggest that after increasing to a time series high from 1984 through 1989, winter skate in Long Island Sound has declined slightly (SAW44 2006).

Figure 1. Winter skate stratified mean weight and number per tow for the winter, spring, and fall NEFSC trawl surveys.

Table 3. Abundance and biomass from NEFSC spring surveys for winter skate for the Gulf of Maine to Mid-Atlantic region (offshore strata 1-30,33-40,61-76). The mean index, $95 \%$ confidence intervals, individual fish weight, minimum, mean, and maximum length, 5 th, 50 th, and 95th percentiles of length, number of nonzero tows, and number of fish caught are presented for 2000-2006.

### 7.2.3.2 Little Skate

NEFSC bottom trawl surveys indicate that little skate are abundant in the inshore and offshore strata in all regions of the northeast US coast, but are most abundant on Georges Bank and in Southern New England (Map 2). In the NEFSC autumn surveys (1975-2005), the annual total catch of little skate in offshore strata reached 6,523 fish in 2003. Calculated on a per tow basis, these spring survey catches equate to maximum stratified mean number per tow indices for the GOM-MA inshore and offshore strata autumn maximum catches equate to indices of 18 fish, or 7.7 kg , per tow in 2003 (Table 6 and Table 7). Recent spring catches have equated to 7.9 fish or 3.3 kg per tow in 2006 ; recent autumn catch equates to 7.6 fish or 3.8 kg per tow in 2005 (Table 6 and Table 7). NEFSC winter survey (2000-2006) annual catches of little skate reached a low of 8,870 fish in 2003, equating to a maximum stratified mean catch per tow of 151 fish or 64 kg per tow (Table 8).

Indices of little skate abundance and biomass from the NEFSC spring survey were stable, reached a peak in 1999, and declined thereafter. Autumn survey indices slightly increased in recent years. Little skate biomass decreased in the spring survey since 1999. Little skate was approaching an overfished status as a result of this decline. However, an increase in biomass in 2007 produced an increase in the three year moving average, resulting in little skate not being listed as overfished in the latest assessment.
Abundance of little skate closely reflects patterns in biomass (Figure 2). Autumn survey biomass and abundance are generally lower than those of spring or winter surveys.

The median length of little skates sampled in the survey reached 44 cm TL in the 2005 autumn survey. The median length of the survey catch was generally stable over the duration of the spring and autumn surveys and is currently about 42 cm TL in the spring and 43 cm TL in the autumn (SAW 442006 ). Length frequency distributions from the NEFSC spring and autumn surveys are presented in the SAW 44 documents and are not reproduced in this SAFE Report. In general, the length frequency distributions for little skate show several modes, most often at $10,20,30$, and 45 cm , which are believed to represent ages $0,1,2$, and 3 and older little skate.

Indices of abundance for little skate are available from Massachusetts Division of Marine Fisheries (MADMF) spring and autumn research trawl surveys in the inshore waters of Massachusetts during 19782006. Since the mid 1990s, MADMF biomass indices have fluctuated without trend. Indices of abundance for little skate are available from Connecticut Department of Environmental Protection (CTDEP) spring and autumn finfish trawl surveys in Long Island Sound during 1984-2006 (1992 and later only for biomass). Little skate are the most abundant species in the skate complex in Long Island Sound, with annual CTDEP survey catches ranging from 142 to 837 skates. CTDEP survey indices suggest a decline in recent years (SAW 44 2006).

Figure 2. Little skate stratified mean weight and number per tow for the winter, spring, and fall NEFSC trawl surveys.

Table 6. Abundance and biomass from NEFSC spring surveys for little skate for the Gulf of Maine to Mid-Atlantic region (offshore strata 1-30, 33-40, 61-76, and inshore strata 1-66). The mean index, $95 \%$ confidence intervals, individual fish weight, minimum, mean, and maximum length, 5 th, 50 th, and 95 th percentiles of length, number of nonzero tows, and number of fish caught are presented for 20002006.

Map 2. Little skate biomass distribution in the winter trawl (2000-2007), spring trawl (2000-2008), summer dredge (2000-2007), and autumn trawl (2000-2007) surveys.

### 7.2.3.3 Barndoor Skate

Barndoor skate are most abundant in the Gulf of Maine, Georges Bank, and Southern New England offshore strata, with very few fish caught in inshore ( $<27$ meters depth) or Mid- Atlantic regions (Map 3). In the NEFSC spring survey (1968-2006), the annual total catch of barndoor skate has ranged from 0 fish (several years during the 1970s and 1980s) to 196 fish in 2006. The NEFSC autumn survey (19632005), has exhibited a similar trend. Recent spring catches have equated to 0.6 fish or 1.7 kg per tow in 2006; recent autumn catch equates to 0.4 fish or 1.0 kg per tow in 2005 (Table 9 and Table 10). Barndoor skate appear to be in a rebuilding phase that began in the 1990s. Since 1990, both spring and autumn survey indices have steadily increased, with the spring survey at the highest value in the time series and the autumn survey nearing the peak values found in the 1960s. In 2007, the NEFSC autumn survey showed a decline in biomass (Figure 3). This reduced the three year moving average; however it remains above the biomass threshold and is not considered to be overfished (Figure 3).

Annual catches of barndoor skate in the NEFSC winter survey (1992-2006) have been higher than those in the spring and autumn surveys. However, no fish were caught in 1992. This increased to 355 in 2006, equating to a maximum stratified mean catch per tow of 3.2 fish or 3.0 kg per tow in 2006 (Table 11).

The minimum length of barndoor skate caught in NEFSC surveys is 20 cm TL ( 8 in ), and the largest individual caught was 136 cm TL ( 54 in ) total length, during the 1963 autumn survey in the Gulf of Maine. The median length of barndoor skate in the survey has been stable in recent years in both the spring and autumn surveys, and is currently $70-75 \mathrm{~cm}$ TL (28-30 in NEFSC 2007). Recent catches include individuals as large as those recorded during the peak abundance of the 1960s, and the large number of fish between 40 and 80 cm TL evident during the 1960s is now apparent in recent surveys.

Figure 3. Barndoor skate stratified mean weight and number per tow for the winter, spring, and fall NEFSC trawl surveys.

Map 3. Barndoor skate biomass distribution in the winter trawl (2000-2007), spring trawl (2000-2008), summer dredge (2000-2007), and autumn trawl (20002007) surveys.

### 7.2.3.4 Thorny Skate

NEFSC bottom trawl surveys indicate that thorny skate are most abundant in the Gulf of Maine and Georges Bank offshore strata, with very few fish caught in inshore ( $<27$ meters depth), Southern New England, or Mid-Atlantic regions (Map 4). NEFSC spring and autumn survey indices for thorny skate have declined continuously over the last 40 years. NEFSC survey indices of thorny skate abundance declined steadily since the late 1970s, reaching historically low values in 2005 and 2006 that are less than $10 \%$ of the peak observed in the 1970 s (Figure 4). The annual total catch of thorny skate in the NEFSC spring survey declined to 29 fish in 2006. This downward trend was also seen in the NEFSC autumn surveys reaching 35 fish in 2005. This equates to 0.2 fish or 0.2 kg per tow in spring 2006 and 0.2 fish or 0.2 kg per tow in autumn 2006 (Table 12 and Table 13).

The median length of thorny skate in the survey catch ranged from 23 cm TL in the 2003 autumn survey to 63 cm in the 1971 autumn survey. The median length of the survey catch trended downward through most of the survey time series, but was stable in recent years in autumn surveys, and is currently 40-50 cm TL (16-20 in; SAW44 2006). Length frequency distributions from the NEFSC spring and autumn show a pattern of decline in abundance of larger individuals consistent with an increase in total mortality over the survey time series.

When the skate FMP was implemented in 2003, thorny skate was listed as overfished. This status remained unchanged since 2003. In 2007, overfishing was determined to be occurring on thorny skate as the $2005-2007$ index was lower than the $2004-2006$ index by $24 \%$.

Figure 4. Thorny skate stratified mean weight and number per tow for the winter, spring, and fall NEFSC trawl surveys.

Thorny skate dominates Canadian catches of skate species, comprising approximately $90 \%$ of rajids caught in survey trawls (Kulka and Miri, 2003). Thorny skate populations in Canadian waters are considered to be a single stock based on movement analyses (Kulka et al. 2006; Templeman, 1984) and biological characteristics. Two surveys are used to examine trends in thorny skate abundance in Canada; these are done in the spring and autumn. The spring survey catches fewer skates than the autumn survey, because the skates move to deeper waters in the spring season. However, the spring survey is the primary survey used in analyses because it is conducted throughout the entire area, whereas the autumn survey does not include a number of NAFO Divisions (Kulka et al. 2006). Similar to USA trends, Canadian indices of thorny skates declined in recent years. In the early 1990s, thorny skate abundance reached its lowest level in history. This was followed by a slight increase; the population stabilized at a low abundance in recent years. While the biomass has remained stable, the areal extent of this species has declined with density increasing near the center of the distribution indicating that hyper-aggregation is probably occurring in this species. This change in distribution is thought to be associated with temperature, because the area of high density coincides with the area of warmest bottom temperatures. Average weight in the spring survey has declined from 2 kg in the early 1970 s to 1.2 kg in 1996, with recent years being around 1.6 kg . The population was divided into immature and mature classes based on length. Immature thorny skates have experienced the largest fluctuations in the skate complex. Since the 1990s, the proportion of mature fish has increased while a decrease is evident in immature fish. A stockrecruitment relationship is evident in this population as a linear relationship exists between female spawning stock and young of the year. Age-based stock assessments are not currently possible owing to a lack of age and growth studies. An index of exploitation or relative F, defined as reported commercial catch/spring research survey biomass index, was examined (Kulka et al. 2006). Relative F has tripled since the mid-1980s, reaching $14 \%$ in 2003-2004. Reduced landings in 2005-2006 lowered the relative F to $4 \%$ (Kulka and Miri, 2007). It is estimated that a relative F of approximately $10 \%$ (equating to catches of 11,000 to $13,000 \mathrm{t}$ ) would allow recovery of the stock. Since 1999 average catch has been approximately 10,000 tons (average relative F or 9\%) (Kulka et al. 2006).

Indices of abundance for thorny skate are available from MADMF spring and autumn research trawl surveys in the inshore waters of Massachusetts for the years 1978-2006. MADMF indices of thorny skate biomass have been variable over the time series, but there is a decreasing trend evident in both the spring and autumn time series. The spring index has stabilized around the median of $0.2 \mathrm{~kg} /$ tow throughout the 2000s, while the autumn index has been below the median of $0.6 \mathrm{~kg} /$ tow since 1994 except for 2001 and 2002 (SAW44 2006).

Table 12. Abundance and biomass from NEFSC spring surveys for thorny skate for the Gulf of Maine to Southern New England region (offshore strata 1-30, 33-40). The mean index, $95 \%$ confidence intervals, individual fish weight, minimum, mean, and maximum length, 5 th, 50th, and 95th percentiles of length, number of nonzero tows, and number of fish caught are presented for 2000-2006.

### 7.2.3.5 Smooth Skate

NEFSC bottom trawl surveys indicate that smooth skate are most abundant in the Gulf of Maine and Georges Bank offshore strata regions, with very few fish caught in inshore ( $<27$ meters depth), Southern New England, or Mid-Atlantic regions (Map 5). Since 2000, the total annual catch of smooth skate in the NEFSC spring surveys has ranged from 30 fish in 2000 to 71 fish in 2006 (Table 14). Since 2000, the total annual catch of smooth skate in the NEFSC autumn surveys has ranged from 55 fish in 2000 to 44 fish in 2006 (Table 15).

The median length of smooth skate in the survey catch in the GOM-SNE offshore region shows no trend over the full survey time series, and is currently at about 40 cm TL (16 in) (SAW44 2006). Length frequency distributions from the NEFSC spring and autumn surveys are presented in NEFSC 2007. In general, the length frequency distributions from the NEFSC spring and autumn surveys in the GOM offshore region show modes at 30 and 50 cm TL.

Indices of smooth skate abundance and biomass from the NEFSC surveys were at a peak during the early 1970s for the spring series and the late 1970s for the autumn series (Figure 5). NEFSC survey indices declined during the 1980s, before stabilizing during the early 1990s at about $25 \%$ of the autumn and $50 \%$ of the spring survey index values of the 1970s. In 2008, smooth skate was determined to be overfished based on the 2007 autumn survey data, because the three year moving average dropped below the threshold. Overfishing is not occurring on this species because the consecutive three-year moving average of the biomass indices did not exceed the maximum threshold which according to the FMP defines when overfishing is occurring

Smooth skate has been divided into five Designatable Units (DUs) based on their distribution in Canadian waters. For more detailed information regarding the 5 DUs, refer to McPhie (2006). Latitudinal differences in depth are apparent; depth increases with latitude. Changes in abundance are variable throughout the DUs. Smooth skate has generally declined throughout its range since the 1970s (Kulka et al. 2006b). The Funk DU appears to have experienced the greatest decline ( $91 \%$ for both adults and juveniles); declines in other DUs have been also been high (approximately 80\%). In contrast to this, in the Hopedale Channel, an increase has occurred. The overall decline in abundance can be partially attributed to fishing activity but other factors are thought to play a role in the trend. The period of decline corresponds to cold water temperatures; an equivalent recovery in abundance has not occurred with the return of warmer water temperatures. Preliminary genetic analysis suggests a difference exists between smooth skate from Grand Banks and the Scotian Shelf; however, this is based on a limited number of samples and requires further analysis (Kulka et al. 2006b).

Figure 5. Smooth skate stratified mean weight and number per tow for the winter, spring, and fall NEFSC trawl surveys.

Table 14. Abundance and biomass from NEFSC spring surveys for smooth skate for the Gulf of Maine to Southern New England region (offshore strata 1-30, 33-40). The mean index, $95 \%$ confidence intervals, individual fish weight, minimum, mean, and maximum length, 5 th, 50th, and 95th percentiles of length, number of nonzero tows, and number of fish caught are presented for 2000-2006.

DRAFT

Map 5. Smooth skate biomass distribution in the winter trawl (2000-2007), spring trawl (2000-2008), summer dredge (2000-2007), and autumn trawl (2000-2007) surveys.

### 7.2.3.6 Clearnose Skate

NEFSC bottom trawl surveys indicate that clearnose skate are most abundant in the Mid-Atlantic offshore and inshore strata regions, with very few fish caught in Southern New England and no fish caught in other survey regions (Map 5). Since 2000, the total annual catch of clearnose skate in the NEFSC spring surveys has ranged from 126 fish in 2000 to 39 fish in 2006 (Table 16). Since 2000, the total annual catch of clearnose skate in the NEFSC autumn surveys has ranged from 61 fish in 2000 to 71 fish in 2006 (Table 17). Recent NEFSC winter survey (2000-2006) annual catches of clearnose skate have ranged from 1,449 fish in 2000 to 1,916 fish in 2006, equating to a maximum stratified mean catch per tow of 9 fish or 10 kg per tow in 2000 and 11 fish or 12 kg per tow in 2006 (Table 18).

The median length of clearnose skate in the spring survey catch has increased over the time series, from about 50 cm TL during the late 1970s to at about 60 cm TL in recent years ( 24 in ; SAW44 2006). The median length of the autumn survey catch has been stable over the time series, and is also at about 60 cm TL. Length frequency distributions from the NEFSC spring and autumn surveys are presented in the SAW 44 documents and are not reproduced in this SAFE Report. In general, the length frequency distributions show a consistent mode at $60-70 \mathrm{~cm}$ TL that may represent the accumulated abundance of several older ages.

NEFSC spring and autumn survey indices for clearnose skate have increased since the mid-1980s, through 2000 and have since declined to about average values (SAW44 2006). Clearnose skate biomass index is currently above the biomass threshold reference point and the $\mathrm{B}_{\text {MSY }}$ proxy and is not considered to be overfished (Table 2). Overfishing is not occurring on this species because the consecutive threeyear moving average of the biomass indices did not exceed the maximum threshold which according to the FMP defines when overfishing is occurring

Indices of abundance for clearnose skate are available from the CTDEP spring and autumn finfish trawl surveys in Long Island Sound for the years 1984-2006 (1992 and later only for biomass). The CTDEP survey has caught very few clearnose skate, with annual catches ranging from 0 to 20 skates through 1998, but the indices have increased in Long Island Sound over the time series.

Indices of abundance for clearnose skate are available from the Virginia Institute of Marine Science (VIMS) trawl survey in Chesapeake Bay and its' tributaries for the years 1988-1998. The VIMS trawl survey indices suggest no trend in clearnose skate abundance over this period (SAW44 2006).

Figure 6. Clearnose skate stratified mean weight and number per tow for the winter, spring, and fall NEFSC trawl surveys.

Table 16. Abundance and biomass from NEFSC spring surveys for clearnose skate for the Mid-Atlantic region (offshore strata 61-76, inshore strata 15-44). The mean index, $95 \%$ confidence intervals, individual fish weight, minimum, mean, and maximum length, 5 th, 50 th, and 95th percentiles of length, number of nonzero tows, and number of fish caught are presented for 2000-2006.

Map 6. Clearnose skate biomass distribution in the winter trawl (2000-2007), spring trawl (2000-2008), summer dredge (2000-2007), and autumn trawl (20002007) surveys.

### 7.2.3.7 Rosette Skate

NEFSC bottom trawl surveys indicate that rosette skate are most abundant in the Mid-Atlantic offshore strata region, with very few fish caught in Southern New England and Georges Bank and no fish caught in the Gulf of Maine or inshore (Map 6). Since 2000, the total annual catch of rosette skate in the NEFSC spring surveys has ranged from 15 fish in 2000 to 8 fish in 2006 (Table 19). Since 2000, the total annual catch of rosette skate in the NEFSC autumn surveys has ranged from 10 fish in 2000 to 24 fish in 2005 (Table 20). Calculated on a per tow basis, these spring survey catches equate to maximum stratified mean number per tow indices for the Mid-Atlantic offshore strata set of about 0.1 fish, or about 0.03 kg , per tow during 2000 and about 0.05 fish, or about 0.01 kg , per tow during 2006 (Table 19 and Table 20).

Recent NEFSC winter survey (2000-2006) annual catches of rosette skate have ranged from 740 fish in 2000 to 513 fish in 2006, equating to a maximum stratified mean catch per tow of 0.7 fish or 0.3 kg per tow in 2000 and 0.8 fish or 0.4 kg per tow in 2006 (Table 21).

The median length of rosette skate in the survey catch has been stable over the spring and autumn time series at about $36-37 \mathrm{~cm}$ TL ( 14 in ; SAW44 2006). Length frequency distributions from the NEFSC spring and autumn surveys are presented in the SAW 30 documents. In general, the length frequency distributions show a consistent mode at $30-40 \mathrm{~cm} \mathrm{TL}$.

Indices of rosette skate abundance and biomass from the NEFSC surveys were at a peak during 19751980, before declining through 1986. NEFSC survey indices for rosette skate increased since 1986 through 2001, declined slightly and recent indices are near the peak values of the late 1970s (Figure 7). Rosette skate biomass index is currently above the biomass threshold reference point and the $\mathrm{B}_{\text {MSY }}$ proxy and is not considered to be overfished. Overfishing is not occurring on this species because the consecutive three-year moving average of the biomass indices did not exceed the maximum threshold which according to the FMP defines when overfishing is occurring

Figure 7. Rosette skate stratified mean weight and number per tow for the winter, spring, and fall NEFSC trawl surveys.

Map 7. Rosette skate biomass distribution in the winter trawl (2000-2007), spring trawl (2000-2008), summer dredge (2000-2007), and autumn trawl (2000-2007) surveys.

### 7.2.4 Life History Characteristics and Biological Reference Points

The Essential Fish Habitat Source Documents prepared by the Northeast Fisheries Science Center (NEFSC) of the National Marine Fisheries Service for each of the seven skate species provide most available biological and habitat information on skates. Any updated information will be provided below. These technical documents are available at http://www.nefsc.noaa.gov/nefsc/habitat/efh/ and contain the following information for each skate species in the northeast complex:

Life history, including a description of the eggs and reproductive habits
Average size, maximum size and size at maturity
Feeding habits
Predators and species associations
Geographical distribution for each life history stage
Habitat characteristics for each life history stage
Status of the stock (in general terms, based on the Massachusetts inshore and NEFSC trawl surveys) A description of research needs for the stock
Graphical representations of stock abundance from NEFSC trawl survey and Massachusetts inshore trawl survey data
Graphical representations of percent occurrence of prey from NEFSC trawl survey data
Please refer to the source documents (http://www.nefsc.noaa.gov/nefsc/habitat/efh/) for more detailed information on the above topics. All additional biological information is presented below.

The seven species of the northeast skate complex follow a similar life history strategy but differ in their biological characteristics. This section describes any information made available after the publication of the EFH documents.

### 7.2.4.1 Winter Skate

Sulikowski et al. (2003) aged winter skate in western Gulf of Maine and determined the oldest age estimated to be 18 and 19 years for females and males, respectively (corresponding length - 94.0 cm and 93.2 cm ). Verification of the periodicity of the vertebral bands was determined to be annual with the opaque band being formed in June - July using marginal increment analysis. Von Bertalanffy Growth parameters for male winter skates were calculated to be $\mathrm{k}=0.074, \mathrm{~L}_{\infty}=121.8 \mathrm{~cm} \mathrm{TL}, \mathrm{t}_{0}=-1.418$; calculated estimates for female winter skates were: $\mathrm{k}=0.059, \mathrm{~L}_{\infty}=137.4 \mathrm{~cm}, \mathrm{t}_{\mathrm{o}}=-1.609$ (Sulikowski et al. 2003). Growth curves fit to data from this study were found to overestimate maximum total length compared to observed lengths. This may result from a low representation of maximum sized individuals. The maximum reported length is 150 cm TL. Maximum sizes examined in the Gulf of Maine were 93.2 cm total length and 94.0 cm total length for males and females, respectively (Sulikowski et al. 2003).

Winter skates are capable of reproducing year-round but exhibit one peak in the annual cycle (Sulikowski et al. 2004). Sulikowski et al. (2004) examined hormone concentrations in samples obtained from the Gulf of Maine. Mature spermatocysts were observed in males throughout the year; females were capable of reproducing throughout the year. Peak reproductive activity occurs during June - August.

Size at maturity has been shown to vary with latitude. Sulikowski et al. (2003) examined winter skates in the Gulf of Maine and determined that males attained a maximum TL of 121.8 cm and 137.4 cm TL for females. Age at maturity in the Gulf of Maine is estimated to be 11 years for males and $11-12$ years in
females (Sulikowski et al. 2005b). Size at maturity is 76 cm for females and 73 cm for males (Sulikowski et al. 2005b).

Sosebee (2005) used body morphometry to determine size at maturity to be approximately 65-73 cm TL for females and 49-60 cm TL for males on samples obtained from the NEFSC trawl survey ranging from Gulf of Maine to Cape Hatteras.

Following its listing as overfished, it was necessary to estimate the required reduction in fishing pressure to rebuild this stock. A Leslie matrix demographic model was used for this purpose. This analysis uses life history parameters (e.g. age-at-maturity, longevity, fecundity) to estimate the exponential growth or decline of the population. These estimates are specific to a particular set of life history parameters and population size. In its simplest form, this model is density independent. It is plausible some of these life history parameters may vary with population size, i.e. they are density dependent; incorporating density dependence is difficult to achieve even in a data rich population. For the purposes of this analysis the population was considered to be in a depleted state with a current growth rate of zero, as estimated from the stable trend in survey data in recent years. Further studies on the fecundity and egg survival of this species would aid in reducing the uncertainty in these input parameters.

For winter skate, the model was constructed using recent estimates of available life history parameters described above. The model was tested to determine feasibility of estimates by comparison of estimated growth rates to known growth rates. NEFSC trawl data was used to estimate the current population growth (or decline) rate. Fishing pressure was then incorporated into the model. For a detailed description of the model construction, please refer to Documents 6 and 7 in Appendix I. Natural mortality was found to range between $0.09 \mathrm{yr}^{-1}$ and $0.17 \mathrm{yr}^{-1}$. It was not possible to construct age-specific natural mortality rate so this range was assumed to apply to all ages. The base case scenario based solely on available life history parameters resulted in an $r_{\text {predicted }}$ of $0.19 \mathrm{yr}^{-1}$. A sensitivity analysis resulted in a range of $\mathrm{r}_{\text {predicted }}$ of 0.15 to $0.25 \mathrm{yr}^{-1}$. Owing to the high level of uncertainty in the input parameters, the model was further tested with a range of scenarios of varying productivities. The size at vulnerability to the NEFSC trawl gear was determined from cumulative size frequency plots. Age at vulnerability was calculated using the size at vulnerability and von Bertalanffy growth parameters. This estimate has a level of uncertainty as the vulnerability of skates to commercial gear may differ to that of the research gear. Examination of the NEFSC trawl survey data provided estimates of population growth and decline throughout the survey. Between 1975 and 1987 the population growth rate was $0.17 \mathrm{yr}^{-1}$ (the maximum observed), while the maximum decline was observed between 1987 and $1993\left(-0.14 \mathrm{yr}^{-1}\right)$. Using the above information the necessary percent reduction in fishing mortality was calculated as $31 \%$ for winter skates.

### 7.2.4.2 Little Skate

Previous age and growth studies conducted on little skate have observed similar size at ages through the northwestern Atlantic (Richards et al. 1963; Johnson, 1979; Waring, 1984; Bigelow and Schroeder, 1953). These studies utilized length frequency plots and rings counted in the vertebral centra to estimate the ages of little skate. For more details on these studies refer to the EFH document (Packer et al. 2003c). Johnson (1979) found a maximum length ( $\mathrm{L}_{\text {max }}$ ) of 60 cm (males) and 62 cm (females) $\mathrm{cm}, \mathrm{A}_{\max }$ of 4 years for both sexes, $\mathrm{L}_{\text {mat }}$ of about 45 cm for both sexes, fecundity of 30 egg cases per year, and maximum age of 8 years. Using Frisk's predictive equations and the NEFSC survey maximum observed length of 62 cm provides estimates of $\mathrm{L}_{\text {mat }}$ of 50 cm and $\mathrm{A}_{\text {mat }}$ of 4 years; using Waring's (1984) $\mathrm{L}_{\infty}$ value of about 53 cm provides an estimate of $\mathrm{L}_{\mathrm{mat}}$ of 43 cm . This differs to age and size at maturity estimates for the Gulf of Maine and northern Massachusetts waters. Ciccia et al. (in review) found $50 \%$ maturity occurs at 9.5 years and 48 cm TL for females and 7.7 years and 46 cm TL for males. Natanson (1993)
performed age and growth experiments on captive little skate from Narragansett Bay, Rhode Island that were injected with the antibiotic oxytetracycline. This methodology can be used to validate the ageing protocol for a species. Frisk and Miller (2006) examined vertebral samples of little skate to identify any latitudinal patterns in the northwestern Atlantic. Maximum observed age was 12.5 years. The oldest aged little skate from the mid-Atlantic was 11 years. The oldest individuals from the Gulf of Maine and Southern New England - Georges Bank were 11 years or older. Von Bertalanffy curves were fit for the northwestern Atlantic ( $\mathrm{k}=0.19, \mathrm{~L}_{\infty}=56.1 \mathrm{~cm} \mathrm{TL}, \mathrm{t}_{\mathrm{o}}=-1.77, \mathrm{p}<0.0001, \mathrm{n}=236$ ) and for individual regions (GOM: $\mathrm{k}=0.18, \mathrm{~L}_{\infty}=59.31 \mathrm{~cm} \mathrm{TL}, \mathrm{t}_{\mathrm{o}}=-1.15, \mathrm{p}<0.0001$; SNE-GB: $\mathrm{k}=0.20, \mathrm{~L}_{\infty}=54.34 \mathrm{~cm}$ TL, $\mathrm{t}_{\mathrm{o}}=-1.22, \mathrm{p}<0.0001$; mid-Atlantic: $\mathrm{k}=0.22, \mathrm{~L}_{\infty}=53.26 \mathrm{~cm}, \mathrm{t}_{\mathrm{o}}=-1.04, \mathrm{p}<0.0001$ ).

Sosebee (2005) used body morphometry to determine size at maturity (male -39 cm TL; females -40 48 cm TL ) on samples obtained from the NEFSC trawl survey ranging from Gulf of Maine to Cape Hatteras. Fecundity was estimated to be 30 eggs per year (Packer et al. 2003 c).

### 7.2.4.3 Barndoor Skate

Barndoor skates have been reported to reach a maximum size of 152 cm and 20 kb weight (Bigelow \& Schroeder, 1953). The maximum observed length in the NEFSC trawl survey was 136 cm total length. In a study conducted in Georges Bank Closed Area II the largest individual observed was 133.5 cm , with total lengths ranging from 20.0 to 133.5 cm . Previous discussions of barndoor skate life history have been limited owing to a lack of appropriate data. To compensate for this, Casey and Myers (1998) used a related species, the common skate (Dipturus batis), as a proxy for biological characteristics. This approach is less desirable compared to directed studies on the species in question. Gedamke et al. (2005) examined barndoor skates in the southern section of Georges Bank Closed Area II. Length at 50\% maturity was 116.3 cm TL and 107.9 cm TL for females and males, respectively. The oldest age observed was 11 years. Age at maturity was estimated to be 6.5 years and 5.8 years for females and males, respectively. The von Bertalanffy parameters were also determined: $\mathrm{L}_{\infty}=166.3 \mathrm{~cm} \mathrm{TL} ; \mathrm{k}=$ $0.1414 \mathrm{yr}^{-1} ; \mathrm{t}_{\mathrm{o}}=-1.2912 \mathrm{yr}$. Based on the predictive equations from Frisk et al. (2001) and the Northeast Fisheries Science Center (NEFSC) survey maximum observed length of $136 \mathrm{~cm} \mathrm{TL}, \mathrm{L}_{\text {mat }}$ is estimated at 102 cm TL and $\mathrm{A}_{\text {mat }}$ is estimated at 8 years (Northeast Fisheries Science Center 2000). In another study, clasper length measurements on males from Georges Bank show that male sexual maturity occurs at approximately 100 cm TL.

Sosebee (2005) used body morphometry to determine the size of maturity (females: 96 to 105 cm TL ; males: 100 cm TL ) on samples obtained from the NEFSC trawl survey ranging from Gulf of Maine to Cape Hatteras. Egg production is estimated to range between $69-85$ eggs/female/year (Parent et al. 2008). As part of a captive breeding program, the egg incubation was determined to range from 342 494 days. As part of the same study, successful hatch rate was $73 \%$ (Parent et al. 2008). Previous fecundity estimates were 47 eggs per year (Packer et al. 2003a). Hatchlings range in size from 193 mm TL, 128 mm disk width and 32 g body mass.

Historical Canadian survey data (e.g., as presented in Casey and Myers (1998) from St. Pierre Bank to Brown's Bank) suggest that a substantial decline in barndoor skate biomass in the northern part of the species' range had occurred by the time that standardized NEFSC surveys began in U.S. waters in 1963. If the barndoor skate in U.S. waters are a part of the same unit stock as that in Canadian waters, then the high indices in the NEFSC surveys during the early 1960s likely indicate a biomass well below $\mathrm{B}_{\text {MSY }}$. The linkage between barndoor skates in U.S. and Canadian waters, however, is unknown. The occurrence of barndoor skate in the autumn survey has been increasing steadily since the 1990s and is approaching levels observed in the 1960s.

### 7.2.4.4 Thorny Skate

Sulikowski et al (2005a) aged thorny skate in western Gulf of Maine and found oldest age estimated to be 16 years for both females and males (corresponding length -105 cm and 103 cm ). Verification of the periodicity of the vertebral bands was determined to be annual with the opaque band being formed in August or September using marginal increment analysis. However, marginal increment analysis was only suitable for use on juvenile thorny skates ( $\leq 80 \mathrm{~cm} \mathrm{TL}$ ). Von Bertalanffy Growth parameters for male thorny skates were calculated to be $\mathrm{k}=0.11, \mathrm{~L}_{\infty}=127 \mathrm{~cm} \mathrm{TL}, \mathrm{t}_{\mathrm{o}}=-0.37$; calculated estimates for female thorny skates were: $\mathrm{k}=0.13, \mathrm{~L}_{\infty}=120 \mathrm{~cm} \mathrm{TL}, \mathrm{t}_{\mathrm{o}}=-0.4$ (Sulikowski et al. 2005a). Growth curves fit to data from this study were found to overestimate maximum total length compared to observed lengths. This may result from a low representation of maximum sized individuals. The maximum observed length from the NEFSC trawl survey is 111 cm TL. Maximum sizes examined in the Gulf of Maine were 103 cm TL and 105 cm TL for males and females, respectively (Sulikowski et al. 2005a).

Sulikowski et al. (2006) used morphological and hormonal criteria to determine the age and size at sexual maturity in the western Gulf of Maine. For females, $50 \%$ maturity occurred at approximately 11 years and 875 mm TL; while for males approximately 10.90 years and 865 mm TL . This species is capable of reproducing year round (Sulikowski et al. 2005a) based on morphological characteristics.

Sosebee (2005) used body morphometry to determine size at maturity to be approximately $36-38 \mathrm{~cm}$ TL for females and 49 cm TL for males on samples obtained from the NEFSC trawl survey ranging from Gulf of Maine to Cape Hatteras.

Parent et al. (2008) estimated mean annual fecundity to be 40.5 eggs per year based on 2 captive females producing 81 eggs in 1 year. The observed hatching success is $37.5 \%$ (Parent et al. 2008).

Following its listing as overfished, it was necessary to estimate the required reduction in fishing pressure to rebuild this stock. A Leslie matrix demographic model was used for this purpose. This analysis uses life history parameters (e.g. age-at-maturity, longevity, fecundity) to estimate the exponential growth or decline of the population. These estimates are specific to a particular set of life history parameters and population size. In its simplest form, this model is density independent. It is plausible some of these life history parameters may vary with population size, i.e. they are density dependent; incorporating density dependence is difficult to achieve even in a data rich population. For the purposes of this analysis the population was considered to be in a depleted state with a current growth rate of zero, as estimated from the stable trend in survey data in recent years. Further studies on the fecundity and egg survival of this species would aid in reducing the uncertainty in these input parameters.

For thorny skate, the model was constructed using recent estimates of available life history parameters described above. The model was tested to determine feasibility of estimates by comparison of estimated growth rates to known growth rates. NEFSC trawl data was used to estimate the current population growth (or decline) rate. Fishing pressure was then incorporated into the model. For a detailed description of the model construction, please refer to Documents 6 and 7 in Appendix I. Natural mortality was found to range between $0.15 \mathrm{yr}^{-1}$ and $0.2 \mathrm{yr}^{-1}$. It was not possible to construct age-specific natural mortality rate so this range was assumed to apply to all ages. The base case scenario based solely on available life history parameters resulted in an $r_{\text {predicted }}$ of $0.14 \mathrm{yr}^{-1}$. A sensitivity analysis resulted in a range of $\mathrm{r}_{\text {predicted }}$ of 0.1 to $0.22 \mathrm{yr}^{-1}$. Owing to the high level of uncertainty in the input parameters, the model was further tested with a range of scenarios of varying productivities. The size at vulnerability to the NEFSC trawl gear was determined from cumulative size frequency plots. Age at vulnerability was calculated using the size at vulnerability and von Bertalanffy growth parameters. This estimate has a level of uncertainty as the vulnerability of skates to commercial gear may differ to that of the research
gear. Examination of the NEFSC trawl survey data provided limited information on population growth owing to the lack of obvious trends throughout the time series. Between 1963 and 1994 the population declined at a lower rate of $-0.026 \mathrm{yr}^{-1}$, which increased to $-0.23 \mathrm{yr}^{-1}$ between 1993 and 1998 Using the above information the necessary percent reduction in fishing mortality was calculated as $34 \%$ for thorny skates.

### 7.2.4.5 Smooth Skate

Natanson et al. (2007) aged smooth skate from New Hampshire and Massachusetts waters. Maximum ages were estimated to be 14 and 15 years for females and males respectively. Longevity was estimated to be 23 years for females and 24 years for males. Male and females exhibited significantly different growth rates. Accordingly different growth models were required to fit the male and female growth data. Parameters for the von Bertalanffy equation for the males were determined to be $\mathrm{k}=0.12, \mathrm{~L}_{\infty}=75.4 \mathrm{~cm}$ TL, with $L_{o}$ required to be set at 11 cm TL (Natanson et al. 2007). Growth models applied to females overestimated the size at birth thus requiring the use of back-calculated data resulting in von Bertalanffy parameters of: $\mathrm{k}=0.12, \mathrm{~L}_{\infty}=69.6 \mathrm{~cm} \mathrm{TL}, \mathrm{L}_{\mathrm{o}}=10 \mathrm{TL}$ (Natanson et al. 2007). Sulikowski et al. (2007) determined, in a study conducted in the Gulf of Maine that in their sample mature females ranged in size from 508 to 630 mm TL and for males 550 to 660 mm TL. Based on morphological characteristics in females (ovary weight, shell gland weight, diameter of largest follicles, and pattern of ovarian follicle development) and histological analysis of males (mature spermatocysts in testes) Sulikowski et al. (2007) determined that in the Gulf of Maine smooth skate are capable of reproducing year round. The reproductive cycles of the two sexes are thought to be synchronous (Sulikowski et al. 2007). Kneebone et al. (2007) examined hormonal concentrations of male and female smooth skate in the Gulf of Maine further confirming the ability of this species to reproduce throughout the year. Information is needed on the fecundity and egg survival of this species.

Sosebee (2005) used body morphometry to determine size at maturity to be approximately $33-49 \mathrm{~cm}$ TL for females and 49 cm TL for males on samples obtained from the NEFSC trawl survey ranging from Gulf of Maine to Cape Hatteras.

Following the methodology used for determining the necessary fishing mortality reduction for winter and thorny skates, construction of a Leslie matrix demographic model was attempted for smooth skate after its recent listing as being overfished. However, some of the required life history parameters are unavailable for smooth skate, e.g. fecundity, first year survival and egg survival. It was necessary to estimate the required reduction in fishing pressure to rebuild this stock. In order to construct a Leslie Matrix for this species, it was necessary to utilize data available for other species in the skate complex (as described in Gedamke 2008; Document 6 in Appendix I). Available data on age-at-maturity, longevity and von Bertalanffy growth parameters were used to estimate natural mortality ( 0.17 to $0.2 \mathrm{yr}^{-1}$ ). It was not possible to construct age-specific natural mortality rate so this range was assumed to apply to all ages. No clear trend is apparent from the NEFSC trawl survey, limiting its use in determining growth rates. The base case scenario based solely on available life history parameters resulted in an $\mathrm{r}_{\text {predicted }}$ of $0.20 \mathrm{yr}^{-1}$. A sensitivity analysis resulted in a range of $\mathrm{r}_{\text {predicted }}$ of 0.12 to $0.35 \mathrm{yr}^{-1}$. These estimates carry a high level of uncertainty owing to the limited input parameters. Based on examination of the spring survey data, the population was declining until the early 1990 s; since 1994 there has been an apparent increase at a rate of $0.12 \mathrm{yr}^{-1}$. A decline is not apparent in the autumn survey since the 1990 s ; the population appears to exhibit some stability in the autumn survey during that time period. Existing fishing restrictions may be sufficient to allow this stock to rebuild.

### 7.2.4.6 Clearnose Skate

Gelsleichter (1998) examined the vertebral centra of clearnose skates that were collected from Chesapeake Bay and the northwest Atlantic Ocean. The oldest male was aged at 5+ years, with the oldest female being 7+ years. This study suggests that clearnose skate experience rapid growth over during a relatively short life span.

Sosebee (2005) used body morphometry to determine size at maturity (females: 59 to 65 cm TL ; males: 56 cm TL ) on samples obtained from the NEFSC trawl survey ranging from Gulf of Maine to Cape Hatteras. Fecundity was estimated to be 35 eggs/year (Packer et al. 2003b). Information is needed on the fecundity and egg survival of this species.

### 7.2.4.7 Rosette Skate

Sosebee (2005) used body morphometry to determine size at maturity (males $=33 \mathrm{~cm} \mathrm{TL}$; females $=33-$ 35 cm TL ) on samples obtained from the NEFSC trawl survey ranging from Gulf of Maine to Cape Hatteras. Age and growth data are currently unavailable for rosette skate. Information is needed on the fecundity and egg survival of this species.

### 7.2.5 Feeding habits

The level of gadids and flatfish have declined since the 1970s while elasmobranchs have increased in number (NEFSC, 1998). Availability of prey or the removal of predation may contribute to this phenomenon (Fogarty \& Murawski, 1998). Grosslein et al (1980) and Nelson (1993) identified a high dietary overlap between yellowtail flounder and little skate. This overlap appeared higher when both species were small and declined with increasing size, thus reducing the overall competition between the species (Nelson, 1993). Garrison \& Link (2000) constructed dietary guilds in the Northeastern United States, including flatfishes and skates. Small to medium little skates were allocated to the amphipod/shrimp guild along with four-spot flounder, windowpane and yellowtail flounder. Little skates shifted to piscivores with increasing size. Winter flounder was allocated to the benthivores guild. Little skate comprises a large proportion of the percentage of biomass in the species composition of seasonal spatial assemblages on Georges Bank (Garrison, 2000). Garrison (2000) does not support the hypothesis of the decline in gadids and flatfish allowing the observed increase in elasmobranchs because strong exploitative competition doesn't appear to drive Georges Bank dynamics. Link et al (2002) discuss the potential high competitive overlap between flatfishes and skate but note body morphology and secondary prey preferences and availability may mitigate this competition. The level of competition between skates and flatfishes is an area that requires more work but is also difficult to achieve. To identify competition the following must be met: "spatiotemporal overlap, similarity of resource utilization, limiting resources and notable population impacts of the interaction" (Link et al., 2002). These factors contribute to the difficulty of proving competition exists in the field. Winter flounder were found to comprise only a small component $(<0.1 \%)$ of diet for 1 or 2 skate species despite the skate complex potential to remove a comparable amount of certain prey species as directed fisheries can (Link \& Sosebee, 2008).

Link and Sosebee (2008) investigated the impact of the consumption by the northeast skate complex on the ecosystem using stomach samples obtained from the NEFSC trawl. Overall the skate complex consumes a small proportion of the biomass contained in the system but they have the potential to have a large impact on some prey species. This impact can be at the same level or even exceed that removed by the fishery for a particular prey species. This study was also described in detail in the SAW 44 documents. The percentage composition of each prey type by maturity stage and species is listed in Table 22. For more complete data regarding the feeding habits and prey composition by species please refer to the SAW 44 documents.

Table 22. Relative means stomach weight on average for the size class and time period available expressed as a percentage of total stomach content weight throughout the time series.

### 7.2.5.1 Winter Skate

Winter skates were divided into three size groups: small ( $<30 \mathrm{~cm} \mathrm{TL}$ ) medium ( 45 cm TL ) and large ( 80 cm TL ). Owing to the difficulties in distinguishing between immature little and winter skates, the small size category was included in the analysis of immature little skates. The amount of food consumed was related to the size of the skate. Medium sized skates consumed approximately 2 kg per year of prey items, while large skates consumed approximately 9 kg per year. The total consumptive demand for this species is estimated to range between 20,000 and $180,000 \mathrm{mt}$ per year. Winter skates are benthivorous and their piscivorous nature was clearly shown by the large portion of the diet formed by forage fishes. Overall, the diet of winter skates was dominated by forage fish, squid and benthic macrofauna. Up to $80,000 \mathrm{mt}$ of a particular prey item can be removed by this skate in any given year.

### 7.2.5.2 Little Skate

Little skates were divided into two size groups: immature ( 20 cm TL ) mature ( 45 cm TL ). Owing to the difficulties in distinguishing between immature little and winter skates, the small size category for winter skate was included in the analysis of immature little skates. The amount of food consumed was related to the size of the skate. Immature skates consumed approximately 500 g per year of prey items, while mature skates consumed approximately 2.5 kg per year. The total consumptive demand for this species is estimated to range between 100,000 and $350,000 \mathrm{mt}$ per year, with total consumption dominated by mature skates. Little skates are benthivorous which was reflected by the large portion of the diet that benthic macrofauna (polychaetes and amphipods) and benthic megafauna (crabs and bivalves) comprised. Overall, the diet of little skates was dominated by benthic invertebrates. Up to $8,000 \mathrm{mt}$ of a particular prey item can be removed by this skate in any given year.

### 7.2.5.3 Barndoor Skate

Barndoor skates were divided into two size groups: immature ( $<60 \mathrm{~cm} \mathrm{TL}$ ) mature ( $>100 \mathrm{~cm} \mathrm{TL}$ ). The amount of food consumed was related to the size of the skate. Immature skates consumed approximately 5 kg per year of prey items, while mature skates consumed approximately 10 to 20 kg per year. The total consumptive demand for this species is estimated to range between 4,000 and $16,000 \mathrm{mt}$ per year, with total consumption dominated by mature skates. Barndoor skates are benthivorous and their piscivorous nature was clearly shown by the large portion of the diet formed by forage fishes. Overall, the diet of barndoor skates was dominated by herrings Pandalid shrimps and Cancer crabs. Up to $8,000 \mathrm{mt}$ of a particular prey item can be removed by this skate in any given year.

### 7.2.5.4 Thorny Skate

Thorny skates were divided into three size groups: small ( 20 cm TL ) medium ( 45 cm TL) and large ( 80 cm TL ). Owing to the difficulties in distinguishing between immature little and winter skates, the small size category was included in the analysis of immature little skates. The amount of food consumed was related to the size of the skate. Small sized skates consumed approximately 500 g per year of prey items, while medium and large skates consumed approximately 1.5 kg and 12 kg per year, respectively. The total consumptive demand for this species is estimated to range between 10,000 and $40,000 \mathrm{mt}$ per year. Thorny skates are benthivorous and their piscivorous nature was clearly shown by the large portion of the diet formed by forage fishes. Overall, the diet of thorny skates was dominated by herrings, squid, polychaetes, silver hake and other fish. Up to $80,000 \mathrm{mt}$ of a particular prey item can be removed by this skate in any given year.

### 7.2.5.5 Smooth Skate

Smooth skates were divided into two size groups: immature ( $20-25 \mathrm{~cm} \mathrm{TL}$ ) mature ( 50 cm TL ). The amount of food consumed was related to the size of the skate. Immature skates consumed approximately $0.5-1 \mathrm{~kg}$ per year of prey items, while mature skates consumed approximately $2-3 \mathrm{~kg}$ per year. The total consumptive demand for this species is estimated to range between 1,000 and $5,000 \mathrm{mt}$ per year, with total consumption dominated by mature skates. Smooth skates are benthivorous which was reflected by the large portion of the diet that benthic megafauna (pandalids and euphausiids) comprised. Overall, the diet of smooth skates was dominated by pandalid shrimp and euphausiids. Up to $2,000 \mathrm{mt}$ of a particular prey item can be removed by this skate in any given year, but values are typically on the order of 500 to $1,000 \mathrm{mt}$.

### 7.2.5.6 Clearnose Skate

Clearnose skates were divided into two size groups: immature ( $45-50 \mathrm{~cm}$ TL) mature ( $60-65 \mathrm{~cm}$ TL). The amount of food consumed was related to the size of the skate. Immature skates consumed approximately $1-2 \mathrm{~kg}$ per year of prey items, while mature skates consumed approximately 5 kg per year. The total consumptive demand for this species is estimated to range between 2,000 and $18,000 \mathrm{mt}$ per year, with total consumption dominated by mature skates. Clearnose skates are benthivorous which was reflected by the large portion of the diet that benthic megafauna (crabs and miscellaneous crustaceans) comprised. Overall, the diet of clearnose skates was dominated by other crabs, Cancer crabs and squids. Up to $8,000-10,000 \mathrm{mt}$ of a particular prey item can be removed by this skate in any given year, but values are typically on the order of 2,000 to $4,000 \mathrm{mt}$.

### 7.2.5.7 Rosette Skate

Rosette skates were divided into two size groups: immature ( 22 cm TL ) mature ( 38 cm TL ). The amount of food consumed was related to the size of the skate. Immature skates consumed approximately 200 g per year of prey items, while mature skates consumed approximately 800 g per year. The total consumptive demand for this species is estimated to range between 50 and 500 mt per year, with total consumption dominated by mature skates. Rosette skates are benthivorous which was reflected by the large portion of the diet that benthic macrofauna (amphipods and polychaetes) and benthic megafauna (crabs and shrimps) comprised. Overall, the diet of rosette skates was dominated by benthic macrofauna and to a lesser extent pandalid shrimps, squids and Cancer crabs. Up to 70 mt of a particular prey item can be removed by this skate in any given year, but more typically $10-30 \mathrm{mt}$.

### 7.2.6 Evaluation of Fishing Mortality and Stock Abundance

The length-based mortality estimators of Beverton and Holt (1956) and Hoenig (1987) were considered for the estimation of fishing mortality rates for winter, little, barndoor, thorny and clearnose skates from length frequency distribution sampled by the NEFSC spring and autumn. At the time of the $44^{\text {th }}$ Stock Assessment Workshop (NEFSC 2007), age and growth data were only available for the 5 species listed above. Recently, age and growth estimates have become available for smooth skates (Natanson et al. 2007) but age information remains unavailable for rosette skates.

SARC 30 (NEFSC 2000) concluded that the Hoenig (1987) estimates are more reliable, and those are the fishing mortality rates (F) referenced below. Estimates were calculated for five year moving groups, or windows of years to smooth the variation in the mortality estimates caused by variations in recruitment
over time. Natural mortality for all species was assumed to be equal to the k parameter in the von Bertalanffy equation based on Frisk et al. (2001) which suggests that the $\mathrm{M} / \mathrm{k}$ ratio for skates is about 1.0 . Various values for L' were used to determine the effect of that parameter.

Gedamke et al. (2007; Document 6 in Appendix I) describe the use of Leslie matrices and life tables in evaluating an elasmobranch species ability to withstand fishing pressure. Demographic analysis such as this, tracks the change over time of the number of individuals in each specified class. In an age-based analysis, the data on age-at-maturity, longevity, fecundity and survivorship are required. These data are not always readily available for the skate species. However, as shown in Gedamke et al. (2007) this method can be used in conjunction with the NEFSC survey data to "solve" for the missing parameter, as exampled by barndoor skate. The Leslie Matrix was used to calculate an $r_{\text {conditional }}$ of $0.41 /$ year for barndoor skate in the absence of fishing pressure. This methodology was applied to the skate species from the northeast skate complex currently listed as overfished.

The following subsections describe estimates of mortality for winter, little, barndoor, thorny and clearnose skates. At the time of analysis, no age and growth parameters were available for smooth and rosette skates, so no mortality estimates have been made.

### 7.2.6.1 Winter Skate

The latest assessment report (SAW 44; NEFSC 2007) described the patterns in mortality estimates for winter skate finding that they are consistent across alternative values of L' in both surveys with high values found in the mid-1970s dropping to low values in the 1980s (NEFSC, 2007). Increases occurred with the onset of the directed fishery through the mid-1990s followed by a decline. There is a lag associated with the moving window estimator, so any increase or decrease will be delayed. The values for F from the autumn survey where L ' is 50 cm are 0.17 in the early part of the time series, drop to a low of 0.02 in 1985, increase to 0.2 in 1997 and have declined to 0.11 in recent years.

For winter skate, the SAW concluded that there are insufficient data on species specific historical landings to determine F or propose $\mathrm{F}_{\text {MSY }}$ or proxy reference points. New techniques of estimating fishing mortality were rejected by the SAW. The SAW approved the continued use of the $75^{\text {th }}$ percentile value of the NEFSC autumn biomass indices for the Gulf of Maine (GOM) to Mid Atlantic (MA) offshore region during 1967-1998 as a proxy for the $\mathrm{B}_{\text {MSY }}$ for winter skate ( $6.46 \mathrm{~kg} /$ tow), and one-half of that value as the threshold biomass reference point for winter skate ( $3.23 \mathrm{~kg} / \mathrm{tow}$ ).

Benoit (2006) estimated the acute discard mortality rate of winter skate on Canadian research vessels. Mortality was determined from visible respiratory movements, i.e., spiracle movement. After 1-2 hours out of water, $50 \%$ of individuals no longer showed respiratory movements. Acute discard mortality for this species was estimated to be at least $50 \%$. This estimate is based solely on time on deck and may vary accordingly with sorting time. This study did not address long-term mortality; effects of injuries sustained in the net remain unknown.

For winter skate, the 2005-2007 NEFSC autumn survey biomass index average of $2.93 \mathrm{~kg} /$ tow is less than the biomass threshold reference point of $3.23 \mathrm{~kg} /$ tow and thus species remains overfished. The 2005 2007 average index is less than the $2004-2006$ index by $4 \%$, but overfishing is not occurring because the percent decline in the consecutive three year moving averages does not exceed the maximum threshold which according to the FMP defines when overfishing is occurring.

### 7.2.6.2 Little Skate

The latest assessment report (SAW 44; NEFSC 2007) described the patterns in mortality estimates for little skate finding that they are less consistent across alternative values of L' and surveys. The lower values of $L$ ' indicate that the force of mortality being exerted at these sizes is almost entirely natural mortality. The trend in mortality estimates for $L^{\prime}=45 \mathrm{~cm}$ TL suggests an increases over the time series at relatively high values between 0.2 and 0.4 .

The use of length-based yield per recruit reference points for little skate in the northeast region is considered to be unreliable by the SAW, due to the uncertainty of cohort slicing for age groups. A threshold F reference is therefore proposed for little skate based on the estimate of the natural mortality rate (M). The SARC approved the continued use of the $75^{\text {th }}$ percentile value of the NEFSC spring survey biomass indices for the GOM-MA inshore and offshore regions during 1982-1999 as a proxy for $\mathrm{B}_{\mathrm{MSY}}$ for little skate ( $6.54 \mathrm{~kg} /$ tow ), and one-half of that value as the threshold biomass reference point for little skate ( $3.27 \mathrm{~kg} /$ tow).

For little skate, the 2005-2007 NEFSC spring survey biomass index average of $3.67 \mathrm{~kg} /$ tow is greater than the biomass threshold reference point of $3.27 \mathrm{~kg} /$ tow. Therefore, little skate is not overfished. The 2005 - 2007 average index is less than the $2004-2006$ index by $20 \%$, but overfishing is not occurring, because the percent decline does not exceed the maximum threshold which according to the FMP defines when overfishing is occurring.

### 7.2.6.3 Barndoor Skate

The latest assessment report (SAW 44; NEFSC 2007) described the patterns in mortality estimates for barndoor skate finding that they are very consistent across alternative values of L' and seasons. The trend is low F until 1975 when estimates become more imprecise because of few sampled fish. Estimates then decline to low values through 2006. The time lag in this estimate of fishing mortality is evident in the delay in the increase in F in the early part of the time series.

For barndoor skate, the SAW concluded that there are insufficient data on species specific historical landings to determine F or propose $\mathrm{F}_{\mathrm{MSY}}$ or proxy reference points. New techniques of estimating fishing mortality were rejected by the SAW. The SAW approved the continued use of the mean value of the NEFSC autumn survey biomass indices for the GOM-SNE offshore region during 1963-1966 as a proxy for $\mathrm{B}_{\text {MSY }}$ for barndoor skate ( $1.62 \mathrm{~kg} /$ tow $)$, and one-half of that value as the threshold biomass reference point for barndoor skate ( $0.81 \mathrm{~kg} /$ tow $)$.

For barndoor skate, the 2005-2007 NEFSC autumn survey biomass index average of $1.00 \mathrm{~kg} /$ tow is greater than the biomass threshold reference point of $0.81 \mathrm{~kg} /$ tow. Therefore, barndoor skate is not overfished. The $2005-2007$ average index is less than the $2004-2006$ index by $14 \%$, but overfishing is not occurring, because the percent decline does not exceed the maximum threshold which according to the FMP defines when overfishing is occurring.

### 7.2.6.4 Thorny Skate

Fishing mortality patterns, as described in the latest assessment report (SAW 44; NEFSC 2007), for thorny skate are also consistent across seasons and alternative values of L' (NEFSC, 2007). There has been a general increase in $F$ estimates over the entire time series. For $L^{\prime}=50 \mathrm{~cm} \mathrm{TL}$, the values in the early part of the time series were less than 0.1 , increased to 0.15 in the 1980s and have since increased to around 0.2 in recent years.

For thorny skate, the SAW concluded that there are insufficient data on species specific historical landings to determine F rates or propose $\mathrm{F}_{\mathrm{MSY}}$ or proxy reference points. New techniques of estimating fishing mortality were rejected by the SARC. The SAW approved the continued use of the $75^{\text {th }}$ percentile value of the NEFSC autumn biomass indices for the GOM-SNE offshore region during 1963-1998 as a proxy for the $\mathrm{B}_{\mathrm{MSY}}$ for thorny skate ( $4.41 \mathrm{~kg} /$ tow), and one-half of that value as the threshold biomass reference point for thorny skate ( $2.20 \mathrm{~kg} / \mathrm{tow}$ ).

For thorny skate, the 2005-2007 NEFSC autumn survey biomass index average of $0.42 \mathrm{~kg} /$ tow is less than the biomass threshold reference point of $2.20 \mathrm{~kg} /$ tow. Therefore, thorny skate is overfished. The 2005 2007 index is lower than the 2004 - 2006 index by $24 \%$, therefore overfishing is occurring.

### 7.2.6.5 Smooth Skate

At time of SAW 44 (NEFSC 2007), age and growth data were unavailable to determine fishing mortality rates. There are insufficient data on species specific historical landings to determine fishing mortality rates or propose $\mathrm{F}_{\text {MSY }}$ reference points. New techniques of estimating F were rejected by the SARC. The SAW approved the continued use of the $75^{\text {th }}$ percentile value of the NEFSC autumn biomass indices for the GOM-SNE offshore region during 1963-1998 as a proxy for the $\mathrm{B}_{\text {MSY }}$ for smooth skate ( $0.31 \mathrm{~kg} /$ tow $)$, and one-half of that value as the threshold biomass reference point for smooth skate ( $0.16 \mathrm{~kg} / \mathrm{tow}$ ).

For smooth skate, the 2005 - 2007 NEFSC autumn survey biomass index average of $0.14 \mathrm{~kg} /$ tow is less than the biomass threshold reference point of $0.16 \mathrm{~kg} /$ tow. Unlike its previous status, smooth skate is now overfished. The 2005-2007 index is less than the $2004-2006$ index by $22 \%$, so overfishing is not occurring because the percent decline does not exceed the maximum threshold which according to the FMP defines when overfishing is occurring.

### 7.2.6.6 Clearnose Skate

Fishing mortality patterns, as described by SAW 44 (NEFSC 2007), for clearnose skate are less consistent between surveys and alternative values of L'. However, there has been a general decreasing trend in F estimates over the time series. The values for $L^{\prime}=50 \mathrm{~cm}$ TL have ranged from 0.3 in the early part of the time series and slowly deceased to 0.2 in recent years.

The SAW concluded that there are insufficient data on species specific historical landings for clearnose skate to determine fishing mortality rates or propose $\mathrm{F}_{\text {MSY }}$ reference points. New techniques of estimating F were rejected by the SARC review panel. The SAW approved the continued use of the mean value of the NEFSC autumn survey biomass indices for the GOM-SNE offshore region during 1975-1998 as a proxy for the $\mathrm{B}_{\text {MSY }}$ for clearnose skate ( $0.56 \mathrm{~kg} /$ tow), and one-half of that value as the threshold biomass reference point for clearnose skate ( $0.28 \mathrm{~kg} /$ tow $)$.

For clearnose skate, the 2005-2007 NEFSC autumn survey biomass index average of $0.64 \mathrm{~kg} / \mathrm{tow}$ is greater than the $\mathrm{B}_{\text {MSY }}$ proxy and the threshold reference points of $0.56 \mathrm{~kg} /$ tow and $0.28 \mathrm{~kg} /$ tow. Clearnose skate is not overfished. The 2003 - 2005 average of 0.63 kg /tow was less than $30 \%$ below the 2002-2004 average of $0.75 \mathrm{~kg} /$ tow, therefore overfishing is not occurring for clearnose skate, because this percent decline does not exceed the maximum threshold which according to the FMP defines when overfishing is occurring.

### 7.2.6.7 Rosette Skate

Frisk's (1999) predictive equations and the NEFSC survey $\mathrm{L}_{\text {max }}$ of 57 cm provide estimates of $\mathrm{L}_{\text {mat }}$ of 46 cm and $\mathrm{A}_{\text {mat }}$ of four years. There are insufficient data on the age and growth of rosette skate to determine F or propose $\mathrm{F}_{\text {MSY }}$ reference points. The SAW report (NEFSC 2007) approved the continued use of the $75^{\text {th }}$ percentile value of the NEFSC autumn survey biomass indices for the Mid-Atlantic offshore region during 1967-1998 as a proxy for $\mathrm{B}_{\mathrm{MSY}}$ for rosette skate ( $0.029 \mathrm{~kg} / \mathrm{tow}$ ), and one-half of that value as the threshold biomass reference point for rosette skate ( $0.015 \mathrm{~kg} /$ tow $)$.

For rosette skate, there are insufficient data on age and growth to determine F. The 2005 - 2007 NEFSC autumn survey biomass index average of $0.06 \mathrm{~kg} /$ tow is above the $\mathrm{B}_{\text {MSY }}$ proxy and threshold reference points of $0.029 \mathrm{~kg} /$ tow and $0.015 \mathrm{~kg} /$ tow. Rosette skate is not overfished. The 2005-2007 index is above the 2004-2006 index, and therefore overfishing is not occurring, because the percent decline does not exceed the maximum threshold which according to the FMP defines when overfishing is occurring.

### 7.2.6.8 SARC Comments

NEFSC survey data were the primary source of information used to derive indices of biomass for the skate species and reference points. The trend of indices of winter skate abundance and biomass from the NEFSC autumn surveys has varied throughout the time serious, with a peak occurring in the mid 1980s. Current NEFSC indices of winter skate abundance are below the time series mean, and are about $20 \%$ of the peak observed during the mid 1980s. Indices of little skate abundance and biomass from the NEFSC spring survey have also varied, with increases beginning in the 1980s, reaching a peak in 1999. This peak has been followed by a steady decline. After a long period of absence from the survey, the presence of barndoor skates in the survey has been steadily increasing since 1990. NEFSC autumn survey indices for thorny skate have declined continuously over the last 40 years, reaching a historically low value in 2005 is less than $10 \%$ of the peak observed in the 1970s. Indices of smooth skate abundance and biomass from the NEFSC autumn survey have not shown an increase since the observed peak in the late 1970s. Recently smooth skate was listed as being overfished. NEFSC spring and autumn survey indices for clearnose skate increased from the mid-1980s through 2000 and have since declined to about average values. Recent indices of rosette skate abundance and biomass from the NEFSC surveys have increased approaching the peak values of the late 1970s.

Assessment data for the northeast skate complex is considered to be poor . Difficulties with species identification have hindered the collection of high quality species specific catch data. This in turn has reduced the number of appropriate models available for the stock assessment of these species. The SARC proposed alternative model-based fishing mortality estimates and new biological reference points. The proposed biological reference points were based on stock-recruit or yield-per-recruit analysis. These were not accepted by the review panel due to a lack of species-specific catch data. Further study is required to determine the reliability of these proposed models to ensure their suitability.

The SARC discussed two methods for estimating fishing mortality rates; models developed by Hoenig (1987) and Gedamke and Hoenig (2006). There was concern about whether the assumptions of both methods were met sufficiently. It was suggested that the reliability of the two methods be tested using simulation methods.

### 7.5 Economic Environment

The purpose of this section is to describe and characterize the various fisheries in which skates are caught. It is meant to supplement and update sections of the 2000 Stock Assessment and Fishery Evaluation (SAFE) Report for the Northeast Skate Complex (NEFMC 2001), completed as part of the FEIS for the original Skate FMP (NEFMC 2003). Descriptive information on the fisheries is included, and where possible, quantitative commercial fishery and economic information is presented.

### 7.5.1 Description of Directed Skate Fisheries

### 7.5.1.1 The Skate Bait Fishery

One of the primary markets for skate products in the northeast U.S. is for bait. Small, whole skates are among the preferred baits for the regional American lobster (Homarus americanus) fishery. Most of the skate bait fishery occurs in southern New England waters, and is largely comprised of little skate (>90\%), with a smaller percentage of winter skate occurring seasonally. The following sections describe the major ports and other aspects of the skate bait fishery.

### 7.5.1.1.1 Rhode Island Bait Fishery

Skates have been targeted commercially in Rhode Island for decades for utilization primarily as lobster bait. The majority of bait skates landed in Rhode Island are little skates, with a small percentage of winter skates. There is also a seasonal gillnet incidental catch fishery as part of the directed monkfish gillnet fishery, in which skates (mostly winter skates) are sold both for lobster bait and as cut wings for processing. Fishermen have indicated that the market for skates as lobster bait has been relatively consistent.

The directed skate fishery by Rhode Island vessels occurs primarily in federal waters less than 40 fathoms from the Rhode Island/Connecticut/New York state waters boundary east to the waters south of Martha's Vineyard and Nantucket out to approximately 69 degrees. The vast majority of the landings are caught south of Block Island in federal waters. Effort on skates increases in state waters seasonally to accommodate the amplified effort in the spring through fall lobster fishery. In terms of the directed lobster bait fishery, it is estimated that between 20-30 Rhode Island otter trawl vessels ranging from 50 70 feet dominate the bait market. Approximately eight of those vessels from RI have identified directed skate bait fishing as their sole source of income between June - October annually, with less than $5 \%$ of their trip revenues from other species during that time.

Dayboat vessels ( $<24$ hours) directing on skates land between $5,000-20,000$ pounds of skates per trip, while trip boats fishing ( $>24$ hours) generally 2 days, land approximately $40,000-50,000$ pounds per trip. Incidental catches of skates from vessels targeting either groundfish or the southern New England mixed trawl fishery (squids, scup, fluke, whiting, mackerel, monkfish, etc.) are estimated at $500-2,000$ pounds and are often sold directly to a lobster vessel (rather than through a dealer). Otherwise, many vessels indicate they do not bother to keep skates caught incidentally due to low market value or deck/hold capacity.

As the number of vessels targeting lobsters has decreased so has the demand for skates. Trap reductions in both the inshore and offshore fisheries as well as the collapse of the LI sound fishery have contributed to the decreased demand. Vessels that used to fish 3,500 traps now fish approximately 1,800 . Skates are the preferred bait for the southern New England inshore and offshore lobster pot fishermen, as the skate meat is tough and holds up longer in the pot than other soft bait choices. Herring, mackerel, and
menhaden are also used for bait, usually on trips of shorter duration, in colder water temperatures, or when skates are in short supply. Although there is an overall decrease in demand maintaining a supply is still very difficult for a variety of reasons. As DAS are adjusted via the Multispecies FMP, fewer days or hours can be allocated to fishing for low value species such as skates. These DAS will be reserved for groundfish or leased to other vessels. Many vessels run out of DAS by December also limiting supply and multispecies vessels are forced to take a 20 day block between March and May, prohibiting the use of a DAS which is a requirement of the directed skate fishery. More recently, high fuel prices are causing vessels to work on more profitable species. Rather than fishing an area where it is known to be largely skate, vessels now need to land a mixed trip (skate \& groundfish) in order to justify the DAS usage.

Skates caught for lobster bait are landed whole by otter trawlers and either sold 1) fresh, 2) fresh salted, or 3 ) salted and strung or bagged for bait by the barrel. Inshore lobster boats usually use $2-3$ skates per string, while offshore boats may use $3-5$ per string. Offshore boats may actually "double bait" the pots during the winter months when anticipated weather conditions prevent the gear from being regularly tended. There has also been a tremendous increase in crabbing during these winter months (avg. $\$ 0.65 / \mathrm{lb})$. The presence of sand fleas and parasites, water temperature, and anticipated soak time between trips are determining factors when factoring in the amount of bait per pot.

Size is a factor that drives the dockside price for bait skates. For the lobster bait market, a "dinner plate" is the preferable size to be strung and placed inside lobster pots. Little and winter skates are rarely sorted prior to landing, as fishermen acknowledge that species identification between little skates and small winter skates is very difficult. Ex-vessel skate prices remain relatively stable at an average of about $\$ 0.08$ - $\$ 0.10$ per pound. Quality and cleanliness of the skate are also factors in determining the price paid by the dealer, rather than just supply and demand. The quantity of skates landed on a particular day has little effect on price because there has been ready supply of skates available for bait from the major dealers, and the demand for lobster bait has been relatively consistent. Numerous draggers and lobster vessels have historically worked out seasonal cooperative business arrangements with a stable pricing agreement for skates.

In Rhode Island, there are two major dealers involved in the skate bait market. One reports supplying skates to 100 lobster businesses located in Point Judith, Wickford, Newport, Westerly, and Jamestown, RI, along with businesses scattered throughout Connecticut and Massachusetts. The company buys from 12-15 vessels throughout the year, and ten employees are charged with offloading, salting, and stringing bait for inshore and offshore lobster vessels. The lobster businesses supplied by the company employ between 2-4 crewmembers per vessel. The other major skate dealer in Rhode Island supplies local Newport, Sakonnet, and New Bedford vessels and numerous offshore lobster vessels fishing in the Gulf of Maine. Skates are supplied to this dealer from draggers working out of Newport and Tiverton, RI and New Bedford, MA.

Approximately eighty percent of the skates landed for bait are sold as strung bait, at about $\$ 1.04$ for a string of three skates, usually 120 strings (of three) per barrel for $\$ 121.00$. Under current lobster pot limitations, the minimum bait costs for inshore areas limited to 800 pots is estimated at $\$ 832$ per trip and $\$ 2,000$ per trip for offshore lobster vessels limited to 1800 pots. Offshore vessels reported carrying between $15-30$ barrels of bait per trip, which could reflect different baiting patterns. Skates are also sold by the barrel unsalted and unstrung ( $\$ 50-\$ 60$ ) or by the barrel unstrung and salted ( $\$ 65$ ). A tremendous volume of salt is used in the bait operations, up to 130,000 pounds weekly during the peak of lobster season. Barrels of skates may weigh between $400-500$ pounds. Menhaden bait (pogies) prices vary between $\$ 50-\$ 70$ per barrel ( $\$ 56$ per 30 gl barrel), depending upon the port and the weight.

Due to direct, independent contracts between draggers and lobster vessels landings of skates are estimated to be under-documented. While bait skates are always landed (rather than transferred at sea) they are not
always reported because they can be sold directly to lobster vessels by non federally permitted vessels, which are not required to report as dealers.

### 7.5.1.1.2 Other Bait Fishery Ports

Vessels from other ports (New Bedford and Martha's Vineyard, MA; Block Island, Long Island, Stonington, CT, and, to a lesser degree, Chatham and Provincetown, MA) have been identified as participating in the directed skate bait fishery to some extent. Suppliers indicate that some of these vessels have independent contracts with lobster vessels and supply them directly with skates on a seasonal basis. Refer to Section 7.5.1.3.6 for a description of skate bait landings by port.

Lobster bait usage varies regionally and from port to port, based upon preference and availability. Some lobstermen in the northern area (north of Cape Cod) prefer herring, mackerel, menhaden and hakes (whiting and red hake) for bait, which hold up in colder water temperatures; however, the larger offshore lobster vessels still indicate a preference for skates and Acadian redfish in their pots. Some offshore boats have indicated they will use soft bait during the summer months when their soak time is shorter. Skates used by the Gulf of Maine vessels are caught by vessels fishing in the southern New England area.

### 7.5.1.1.3 The Southern New England Sink Gillnet Fishery

The southern New England sink gillnet fishery targets winter skates seasonally along with monkfish. Highest catch rates are in the early spring and late fall when the boats are targeting monkfish, at about a 5:1 average ratio of skates to monkfish. Little skates are also caught incidentally year-round in gillnets and sold for bait. Several gillnetters indicated that they keep the bodies of the winter skates cut for wings and also salt them for bait. Gillnetters have become more dependent upon incidental skate catch due to cutbacks in their fishery mandated by both the Monkfish and Multispecies FMPs. Gillnet vessels use 12inch mesh when monkfishing, catching larger skates. Southern New England fishermen have reported increased catches of barndoor skates in the last few years.

### 7.5.1.1.4 Regulatory Issues for the Bait Fishery

Two existing and significant regulatory limitations on the directed bait skate fishery include lobster regulations which mandate a decrease in pot limits and groundfish DAS requirements. A majority of directed skate fishermen fish in federal waters, possess multispecies permits, and fish for skates with gear capable of catching multispecies. This, in turn, means that they must use a DAS when fishing for skates unless fishing in an exempted fishery. There are currently two exempted skate fisheries in the Southern New England Exemption Area; one gillnet fishery and one deepwater trawl fishery (see Error! Reference source not found. for a map of these areas).

Effort in the skate fishery is reduced during the winter months because it becomes more difficult to budget DAS usage, especially for vessels that fish for groundfish either seasonally or year-round (in addition to directing on skates). Due to effort reductions in the multispecies fishery (e.g., Amendment 13, Framework 42), the majority of full-time skate vessels are presently limited to less than 50 DAS per fishing year.

Since the implementation of the Skate FMP in 2003, vessels fishing in the skate bait fishery that wish to be exempt from the skate possession limits (see Section Error! Reference source not found.) must acquire a Letter of Authorization (LOA) from the Regional Administrator. A number of vessels remain under the mistaken impression that this LOA also exempts them from DAS requirements. However, these vessels must still be fishing in an exempted fishery to be exempt from DAS.

### 7.5.1.2 The Skate Wing Fishery

The other primary market for skates in the region is the wing market. Larger skates, mostly captured by trawl gear, have their pectoral flaps, or wings, cut off and sold into this market. Attempts to develop domestic markets were short-lived, and the bulk of the skate wing market remains overseas. Winter, thorny, and barndoor skates are considered sufficient in size for processing of wings, but due to their overfished status, possession and landing of thorny and barndoor skates has been prohibited since 2003. Winter skate is therefore the dominant component of the wing fishery, but illegal thorny and barndoor wings still occasionally occur in landings (Table 32).

Table 32. Preliminary skate wing fishery species composition (\% total) in sampled landings by state (2006-2007). Source: Experimental skate wing dockside sampling process, NMFS Fisheries Statistics Office.

| Species | ME | MA | RI | NJ |
| :---: | :---: | :---: | :---: | :---: |
| Winter | 95.4 | 93.3 | 95.8 | 61.7 |
| Thorny | 3.0 | 6.7 | 0.2 | 0.0 |
| Barndoor | 1.6 | 0.0 | 0.1 | 0.0 |
| Little* | 0.0 | 0.0 | 4.0 | 14.9 |
| Clearnose | 0.0 | 0.0 | 0.0 | 23.4 |
| Smooth | 0.0 | 0.0 | 0.0 | 0.0 |
| Rosette | 0.0 | 0.0 | 0.0 | 0.0 |
| N wings sampled | 3,931 | 11,360 | 3,761 | 2,049 |
| «likely misidentified winter skate |  |  |  |  |

Only in recent years have skate wing landings been identified separately from general skate landings. Landed skate wings are seldom identified to species by dealers. Skate processors buy whole, hand-cut, and/or onboard machine-cut skates from vessels primarily out of Massachusetts and Rhode Island. Because of the need to cut the wings, it is relatively labor-intensive to fish for skates. Participation in the skate wing fishery, however, has recently grown due to increasing restrictions on other, more profitable groundfish species. It is assumed that more vessels land skate wings as an incidental catch in mixed fisheries than as a targeted species.

New Bedford emerged early-on as the leader in production, both in landed and processed skate wings, although skate wings are landed in ports throughout the Gulf of Maine and extending down into the MidAtlantic. New Bedford still lands and processes the greatest share of skate wings. Vessels landing skate wings in ports like Portland, ME, Portsmouth, NH, and Gloucester, MA are likely to be landing them incidentally while fishing for species like groundfish and monkfish. Refer to Section 7.5.1.3.6 for a description of skate wing landings by port.

The current market for skate wings remains primarily an export market. France, Korea, and Greece are the leading importers. There is a limited domestic demand for processed skate wings from the white tablecloth restaurant business. Winter skates landed by gillnet vessels are reported to go almost exclusively to the wing market. Fishermen indicate that dealers prefer large-sized winter skates for the wing market (over three pounds live weight).

### 7.5.1.3 Commercial Fishery Landings

This section presents available commercial landings information for the northeast region skate complex from 2000-2007. This includes total annual landings; landings by market category; landings by state, gear type, port, and area fished; Canadian skate landings; and recreational skate landings. For data previous to 2000, refer to the 2000 SAFE Report (NEFMC 2001).

Note that NMFS estimates commercial skate landings from the dealer weighout database and reports total skate landings according to live weight (i.e., the weight of the whole skate). This means that a conversion factor is applied to all wing landings so that the estimated weight of the entire skate is reported and not just the wings. While live weight is necessary to consider from a biological and stock assessment perspective, it is important to remember that vessels' revenues associated with skate landings are for landed weight (vessels in the wing fishery only make money for the weight of wings they sell, not the weight of the entire skate from which the wings came).

### 7.5.1.3.1 Total Commercial Landings

Due to the relative absence of recreational skate fisheries, virtually all skate landings are derived from regional commercial fisheries. Skates have been reported in New England fishery landings since the late 1800s. However, commercial fishery landings never exceeded several hundred metric tons until the advent of distant-water fleets during the 1960s. Skate landings reached $9,500 \mathrm{mt}$ in 1969 , but declined quickly during the 1970s, falling to 800 mt in 1981 (Figure 8). Landings have since increased substantially, partially in response to increased demand for lobster bait and the increased export market for skate wings. In 2007, skate landings were the highest ever recorded, exceeding $19,000 \mathrm{mt}$. The increased demand for skate products since the mid-1980s has concurrently resulted in declining discard rates for skates (Figure 8).

Amendment 3 was implemented on June 16, 2010, near the beginning of the 2010 fishing year. Landings from 2009 to 2010 decline by $28 \%$ to $15,836 \mathrm{mt}$, largely from reductions in the wing fishery. Skate transfers at sea for bait, reported on VTRs, also declined by $50 \%$ to $1,427 \mathrm{mt}$. State landings in the figure below include landings reports by dealers which have no or aggregate federal permit numbers, but for actual monitoring purposes, the NE Regional Office determines whether the vessel has a federal permit at the time of landing. State landings in the figure below are henceforth underestimated, compared to TAL monitoring data.

Figure 8. Annual U.S. skate landings (mt), 1994-2010 fishing years. The Skate Complex FMP was implemented in 2003.

### 7.5.1.3.2 <br> Landings by fishery

Federal permitted seafood dealers report skate landings by intended market, recorded with either a disposition or utility code. Although slight differences occur (and the disposition code began in 1996), nearly all of the skate landings are recorded as 'bait' or 'food or unknown' and the two codes agree in the vast majority of cases. In addition, vessel operators report landings and transfers at sea (dealer=000002) by vessel trip reports (VTR) since 1994.

Skate landings reported for the food market began at least as early as 1963 , with $26,000 \mathrm{lbs}$. of landings (Table 33). Wing landings rose to 35 million pounds in 2003 and then varied between 24.5 and 32.5 million pounds since then, before declining to 22.2 million pounds in 2010. Over the period 1995-2006 (the period used in Amendment 3 to allocate landings to wing and bait fisheries), wing landings averaged $73.2 \%$ of total skate landings. From 1995-2009, before Amendment 3 implementation, wing landings averaged $72.5 \%$ of total landings.

Reported bait landings increased rapidly from the first reports in 1983 to 12.2 million pounds in 1992, before declining to relatively low levels from 1995-2003. During this time, it appeared that reported transfers at sea of skates for bait replaced the bait landings reported to dealers, peaking at 15 million pounds in 2000. Bait landings reported by dealers increase by about $10 \%$ to 10.0 million pounds during fishing year 2010. Bait landings reported by dealers accounted for 6.7 of total skate landings during 1995-2006 and 9.8\% of landings during 1995-2009. Transfers of sea of skates for bait averaged $20.1 \%$
of total skate landings during 1995-2006 and 17.7\% of total skate landings during 1995-2009. Taken together, the bait landings sold to dealers or transferred at sea averaged $26.8 \%$ of total skate landings during 1995-2006 and 27.5\% during 1995-2009.

On a price per whole pound basis ${ }^{1}$, skate prices for wings were two to two and half times those paid by dealers for bait (Table 33). In 2010, however, bait prices increased to $\$ 0.25$ per pound, while prices for wings increased slightly to $\$ 0.23$ per whole pound (or $\$ 0.52$ for wings). It should be noted that in 2010, skate wing prices varied considerably as the supply of skate wings changed in response to skate possession limit changes.

Nearly all skate bait landings are landed in whole form (Table ???). Some dealers have reported landings of wings for the bait market, but these reports may either be inaccurate or represent landings of wings that cannot be marketed for food. On the other hand, since 1995 a significant amount of landings for the skate wing market (reported as 'food or unknown' on dealer reports were landed in whole form, presumably cut shoreside with the carcasses either sold as bait or disposed as unmarketable. This practice (landing whole skates for the wing market) seemed to be more prevalent from 1995 to 2003, but it appears to coincide with a period of low landings reports by dealers. Thus some of these landings of whole skates for the wing market were probably really destined for the skate market and not reported or coded accurately on the dealer reports. It would be difficult to distinguish the difference in the dealer report data without making assumptions.

### 7.5.1.3.3 Landings by State

Table 35 presents commercial landings of skates by individual states from 2003-2010. Massachusetts and Rhode Island continue to dominate the skate fishery, averaging about $20-30$ million lb annually across the time series. Skate landings from Massachusetts and Rhode Island comprised $80-94 \%$ of the total reported annual skate landings during this period. Rhode Island landings have remained fairly consistent but declined in 2009 and 2010, while Massachusetts landings have increased significantly since 2000, before dropping in 2010. New Jersey, New York, Connecticut, Maine, New Hampshire, and Virginia land relatively small amounts of skates. Reported skate landings from Maine and New

Hampshire have decreased in recent years. Very few skates are landed in Maryland and North Carolina, and Delaware (no listed due to confidentiality) reported minimal skate landings for the time series.

From 2009 to 2010, bait landings increased by 7 percent, mostly from increases in RI where bait landings increased by $10 \%$. Wing landings, on the other hand, declined by $33 \%$ to 22 million pounds, mostly in MA. Wing landings in RI were about the same as they were in 2009, but less than half of the amounts in 2003 to 2010. It may be that the utility code reported by dealers for landings in RI (where most bait landings occur) were misclassified before 2009. Skate wing landings in NJ and NY increased by 22 and 42 percent, respectively.

Table 35. U.S. skate landings (thousands lbs) by state, 2003-2010. Source: NMFS Dealer reports.

### 7.5.1.3.4 Landings by Market Category

The Skate FMP implemented new reporting requirements for skates beginning in 2003. A list of the available skate codes in the dealer weighout database is included in Table 36. Federally permitted dealers report most of the skate wings they purchase by two separate market categories: unclassified wings (code 3651) or "big skate" (code 3671). They mostly report whole/bait skate landings as little skate (code 3660) or unclassified whole skates (code 3650). Landings reported as little skate are known to include amounts of juvenile winter skate. Although reporting of skate landings by species has been encouraged, species identification by vessels and dealers remains problematic, and most landings continue to be unclassified or misrepresented (Figure 9). This mis-identification in the landings declined in 2010 but still remains problematic.

While the landings by market category from the dealer weighout data may not be entirely complete, they can be examined to identify the general proportion of skate landings that are used for either the lobster bait market or the seafood market. They can also be disaggregated into individual ports to characterize skate fishing activity in the port.

According to Table 37, more pounds of skates are caught for the wing market than for the bait market. For the time series, skate wing landings (live weight) accounted for $68-75 \%$ of the total landings. In general, the proportion of skate landings reported as wings has increased since 2000, which is also apparent in landings data for the state of Massachusetts, presented in Table 35, but declined in 2010 mostly from Amendment 3 regulations.

Revenues from wing landings are generated from landed weight. Wing landings receive a significantly higher ex-vessel price than bait landings, as fewer landed pounds of wings generated substantially higher
revenues than the larger amounts of whole skates landed. Based on the data summarized in Table 37, the price for whole skates averaged $\$ 0.07-0.12$ per lb, and the price for skate wings averaged $\$ 0.33-0.60$ per lb . The price (unadjusted) for whole skates has remained relatively constant, whereas the price for skate wings has been increasing since 2001, but leveled off since 2006. Prices for wings in 2010 averaged $\$ 0.52$ and the wing landings were $68 \%$ of the total.

Table 36. List of skate species and market codes used in the dealer weighout database since 2003. Note: Big skate is an alternative common name for winter skate (Leucoraja ocellata), and does not indicate the Pacific big skate (Raja binoculata).

### 7.5.1.3.5 Landings by Gear

Table 38 presents annual skate landings (2003-2010) from the dealer SAFIS database by gear type and by market category as a percentage of the annual total. Otter trawl is the primary gear used to land skates. Approximately $43-73 \%$ of the total skate landings during this period were captured by trawl gear. About $25-30 \%$ of the skates caught with otter trawls are landed for the lobster bait market, with the other 70$75 \%$ landed for the wing market (Table 38). Almost all skates caught for the lobster bait fishery are caught with a trawl. Gillnets are the secondary gear used to land skates. Almost all skates that are caught with gillnets are landed as wings. Between 2003 and 2010, $95-98 \%$ of the total gillnet landings of skates were wings (Table 38). Gillnet landings of skates increased over the time series, representing $25 \%$ of the total landings in 2003, but up to $47 \%$ of the total in 2010.

Other gears in which skates are consistently caught include traps, hook gear (including longlines), and scallop dredges. The overall contribution of skate landings from gears other than trawl and gillnets is relatively insignificant.

Table 38. Annual (fishing year) skate landings (live weight, thousands lbs) by gear type and market category as a percentage of total skate landings. Source: Dealer SAFIS Database, NMFS

### 7.5.1.3.6 Landings by port

Table 39 present annual skate wing landings (from the dealer SAFIS database) by port for 2003-2010. The top 15 ports in 2003-2009 represented over $93 \%$ of the total skate landings in the region. In 2010, the top 15 ports contributed to only $88 \%$ of skate wing landings, suggesting that the top ports may have been impacted more by the Amendment 3 regulations than ports with lower skate wing landings. New Bedford suffered a $72 \%$ decline in reported landings for the skate wing market.

Currently, the top ports landing whole skates for lobster bait are:

2003-2010

1. Point Judith
2. Tiverton
3. New Bedford
4. Newport
5. Stonington

2010

1. Point Judith
2. Newport
3. Fall River
4. Chatham
5. Belford

Currently, the top ports landing skate wings are:

2003-2010

1. New Bedford
2. Chatham
3. Point Judith
4. Boston
5. Barnegat Light

2010

1. Chatham
2. New Bedford
3. Point Judith
4. Gloucester
5. Barnegat Light

New Bedford, MA and Chatham still dominate skate landings, averaging over $43 \%$ of the total skate landings in 2010. New Bedford and Chatham dominate skate wing landings, and Point Judith dominates skate bait landings. Between 2003-2010, an average of $97 \%$ of New Bedford's skate landings were classified as wings. All of New Bedford's 2010 landings were classified as wings. An average of $78 \%$ of Point Judith's skate landings were classified as whole skates (Table 39). Wing landings as a percentage in Point Judith increased to $33 \%$ in 2009 and 2010. Since 2000, skate wing landings in Provincetown, MA have declined, while landings in Chatham, MA have increased substantially.

Table 39. Annual skate landings (live weight, thousands lbs) for top 15 ports by market category and as a percentage of total skate landings (2003-2010). Source: Dealer SAFIS Database, NEFSC

### 7.5.1.3.7 Landings by Day-at-Sea Program (to be updated)

Upon implementation of the Skate FMP in 2003, vessels were required to fish on a Multispecies, Monkfish, or Scallop Day-at-Sea (DAS) to possess skates, unless fishing in an exempted fishery. This management measure was an indirect method to control effort in the skate fishery, which has a great deal of overlap with these fisheries. The tables and figures below characterize the skate landings in each of these DAS programs.

The vast majority (73-84\%) of skate landings from a DAS program are landed on Multispecies A DAS (Table 40). During the time series, $15.3-22.2$ million lb of skates were landed in this program. This program represents the majority of effort in the northeast groundfish fleet. Landings by vessels fishing on Monkfish DAS have been relatively stable at $0.6-1.9$ million lb per year. Vessels fishing on combination Monkfish/Multispecies A DAS landed $2.0-5.6$ million lb annually. Skate landings by vessels fishing on Scallop DAS have been relatively negligible. Skates captured by scallop dredge vessels tend to be discarded.

Landings in the Multispecies B DAS program have increased since its implementation in 2004 (Table 40). This program was designed to allow vessels to target healthy groundfish stocks, primarily haddock, in specific areas using certain gears without using their A DAS. Since B DAS vessels fishing with trawl gear may only possess up to 500 lb of skates, the increase in skate landings observed in 2007 in this program was mainly attributed to vessels fishing with gillnets (Figure 12). Virtually all of the skate landings in the Multispecies B DAS program are landed for the wing market (Figure 10).

In the earlier parts of this time series, skate wing landings by trawl vessels far exceeded the landings of other gears on A DAS. Since 2003, however, gillnets have become the dominant gear landing skate wings on A DAS (Figure 11). As noted above, gillnets are also the primary gear for skate wings in the B DAS program.

### 7.5.1.4 Fishing Areas

Vessels landing skates for the wing market either target skates on Georges Bank, in the Great South Channel near Cape Cod, MA, or west of the Nantucket Lightship Area in Southern New England waters. Maps of effort distributions are presented in Section ???, which analyzes the effect of skate management areas on skate fishing. Vessels using gillnets often target skates to supply the wing market by fishing east of Cape Cod, MA.

Other vessels land skates for the wing market while fishing for other species. Vessels fishing for groundfish and in particularly flounders often land an incidental catch of skates. These vessels often fish in Massachusetts Bay and on Georges Bank. Some vessels fishing for scallops using dredges also land skates, but in particular scallop vessels with general category permits that fished in the Great South Channel often land skates. There is also a mixed monkfish/skate fishery that occurs west of the Nantucket Lightship Area and off Northern NJ, near Point Pleasant.

A skate fishery in RI and to a lesser extent in New Bedford supplies a lobster bait market, by landing whole skates while fishing inshore waters of Southern New England. Most of these vessels use trawls and often fish in an exempted fishery.

According to landings data, assigned to statistical fishing area with matching VTR reports, the majority of skate wing landings from vessels using trawls are caught on Georges Bank and landed in MA (Table 39 ???). These wing landings fell off dramatically in 2010, much more than in other states or other areas, possibly related to new skate and groundfish rules. Nearly all of the skate wing landings decrease occurred in New Bedford by vessels using trawls, a pattern not reflected nearly as dramatically in other ports in MA or elsewhere.

Skate wing landings in MA by vessels using gillnets were more evenly split, $60 \%$ from Georges Bank and 30\% from Southern New England (Table 39???). And despite the reduced possession limit for vessels using a gillnet while using a Category B Multispecies DAS ${ }^{2}$ and the Amendment 3 skate possession limits, the landings by vessels using gillnets declined relatively little in 2010. In fact significant landings in RI and NY from Southern New England waters remained nearly steady and in NJ from the MidAtlantic waters actually increased in 2010.

Some whole skate landings in MA from the Gulf of Maine and RI from Southern New England waters were reported for vessels using gillnets (Table 40???). These landings were either relatively stable in 2010 or increased by about $200,000 \mathrm{lbs}$ and most of these landings were probably landed in whole form for the wing market, with carcasses being sold for bait. Most of the whole skate landings for the bait market come from Southern New England waters (Table 40??) and are caught by vessels using trawls. MA landings primarily come from Southern New England waters and dropped by about 2/3rds in 2010. The majority of whole skate landings by trawl vessels occurred in RI from Southern New England waters and declined by about $15 \%$ from fishing year 2009 to 2010.

Table 42. Whole skate landings (live wt, thousand lbs.) for vessels using trawls and gillnets by fishing year, state, and area.

### 7.5.1.5 Canadian skate landings

Historical information on Canadian skate fisheries and management was described in the 2000 SAFE Report for skates, and can also be found in Swain et al. (2006) and Kulka et al. (2007). Prior to 1994, skates were only caught incidentally in Canadian fisheries like those for groundfish. However, a Canadian directed skate fishery was initiated in 1994 as a response to closures in the traditional Canadian groundfish fishery and an increasing international market for skate wings. Canadian skate catches have declined from 4200 mt in 1994, to 1100 mt in 2006 (Kulka et al. 2007).

The directed skate fishery evolved on the eastern Scotian Shelf, in NAFO Divisions 4Vs and 4W (Map 20) and targets primarily winter skate ( $\sim 90 \%$ ) with a small bycatch of thorny skate (less than $10 \%$ ) (NEFMC 2001). A Total Allowable Catch (TAC) for the directed skate fishery in 4VsW was set in 1994 and every year thereafter to ensure that the fishery would not expand beyond sustainable levels. The TAC has been lowered almost every year since 1994 in response to interim assessments, concerns over the response of winter skate to directed fishing, and decreasing participation in the fishery. In 1994, winter skate landings exceeded 2000 mt , but as the quota has been progressively reduced, landings have fallen to less than 300 mt since 2001 (Swain et al. 2006) (Table 43). In 2005, winter skate in the southern Gulf of St. Lawrence was designated as endangered by the Committee on the Status of Endangered Wildlife in Canada. Winter skate on the eastern Scotian Shelf was also designated as threatened (Swain et al. 2006). In addition to fishing mortality, observed winter skate population declines may be influenced by natural mortality, specifically increased predation by seals (Swain et al. 2006).

While winter skate range from south of Georges Bank to the Gulf of St. Lawrence, they are near their northern limit of distribution on the offshore banks of the eastern Scotian Shelf. From observations of discontinuities in distribution, Canadian scientists believe that the winter skates in Division 4VsW are probably part of a separate stock (although very little work has been completed on skate stock delineation). Frisk et al. (2008), however, hypothesize that population connectivity exists between winter skates on the Scotian Shelf and on Georges Bank, based on trends in U.S. and Canadian trawl survey data.

Table 43. Estimated winter skate removals (tons) from NAFO Areas 4VsW, 1999-2004 (Swain et al. 2006).

| Calendar year | Skate catch (mt) |
| :---: | :---: |
| 1999 | 592 |
| 2000 | 358 |
| 2001 | 235 |
| 2002 | 278 |
| 2003 | 39 |
| 2004 | 233 |

In addition to the directed winter skate fishery in Division 4VsW, there is a fishery for thorny skates in the Grand Banks, Divisions 3L, 3N, 3O, and 3Ps depicted in Map 20. Table 44 summarizes the skate landings from these areas. Since 1998, the gears used in this fishery have been evenly distributed between gillnet, longline, and otter trawl.

Thorny skate range from Greenland to South Carolina in the northwest Atlantic, with a center of abundance on the Grand Banks. It is not presently known if the population comprises a single stock, or if there is structure between U.S., Canada, and other regional populations. Canadian assessments indicate that the thorny skate population in Areas 3LNOPs has been near historic low levels for the last 14 years, and there is evidence of hyper-aggregation (Kulka et al. 2007). The current TACs for thorny skate in Canada exceed the recommended level of exploitation to rebuild the stock.

Total Canadian landings had a similar trend as described above, but since 1997 most of the landings happened in Newfoundland and Labrador. Total skate landings (see table below) since last updated in Kulka et al. (2007) remained relatively stable, between 1,000 and $1,500 \mathrm{mt}$, nearly all in the Newfoundland and Labrador province, probably having little in common with the skate stocks along the US coastline. Skate landings in the contiguous Nova Scotia province and in particularly from the Scotia/Fundy region declined from 250 - 800 mt during 1998-2007 to negligible amounts in 2008 and 2009.

### 7.5.1.6 Recreational skate catches

In general, skates have little to no recreational value and are not intentionally pursued in any recreational fisheries. Catch information for Atlantic coast skates from the Marine Recreational Fishery Statistics Survey (MRFSS) is presented in Table 46 and Table 49. Recreational skate catches between 2000 and 2009 ranged from 1.4 million fish in 2001 to 3.3 million fish in 2003 (Table 46). Recreational skate catch estimates have declined since 2006 to 1.8 million fish.

Recreational harvest of skates (MRFSS A+B1 data), where skates were retained and/or killed by the angler, represent only $0.4-3.0 \%$ of the estimated total catch during this time period Table 48. The vast majority of skates caught by recreational anglers are therefore considered released alive, but do not account for post-release mortality caused by hooking and handling.

New Jersey, New York, North Carolina, Massachusetts, and Virginia reported the largest recreational skate catches over the time series, but the annual catch estimates for each of those states appear to be rather inconsistent and do not illustrate any clear trends. Recreational fishers in Maine did not report
catching any skates in 2004, 2006 to 2009. Catch estimates from Delaware, Maryland, Virginia, and North Carolina suggest that some of the skates caught recreationally are either clearnose or rosette skate, or other species of skates that are not included in the northeast complex (Table 49).

Reliability of skate recreational catch estimates from MRFSS is a concern. Many summaries given in the table below include estimates with a proportional standard error (PSE) of 0.2 or more, indicating that they are not well estimated. In particular, this applies to landings and dead discards (A+B1), even for coastwide annual summaries. PSEs provide a measure of precision and represent another way to express error associated with a point estimate. Estimates with a PSE of 0.2 or less are considered to be more reliable than those with higher PSEs, and generally, PSEs of 0.2 or less are considered acceptable for fisheries data. Total catch estimates ( $\mathrm{A}+\mathrm{B} 1+\mathrm{B} 2$ ), however, appear to be more reliable than harvest estimates (A+B1 only). Since skates are not valuable and heavily-fished recreational species, the number of MRFSS intercepts from which these estimates are derived is likely to have been very low. The fewer intercepts from which to extrapolate total catch estimates there are, the less reliable the total catch estimates will be.

Table 46. Recreational skate (Family Rajidae) catch (A+B1+B2; thousand fish) on Atlantic Coast, 19812009. Type A catch is fish that are landed in a form that can be identified by trained interviewers. Type B1 catch is fish that are used for bait, released dead, or filleted - they are killed, but identification is by individual anglers rather than trained interviewers. Type B2 catch are fish that are released alive. Source NMFS Marine Recreational Fisheries Statistics (MRFSS): http://www.st.nmfs.noaa.gov/pls/webpls/MR HELP.SPECIES. Estimates with proportional standard error (PSE) of 0.20 or less (available via the above website) are considered more reliable than those with higher PSEs.

Table 49. Recreational catch ( $\mathbf{A}+\mathbf{B 1}+\mathbf{B} 2$; thousand fish) by species, mode, and distance from shore. The "All" category includes catches identified by species.

### 7.5.1.7 Discards

Commercial fishery discard estimates of skates, for all species combined, were calculated as described in SAW 44 (NEFSC 2006). The method for calculating discards was revised from the method used in the previous skate assessment (SAW 30). The estimates were derived by a ratio-estimator approach, using discard/kept ratios, as described by Rago et al. (2005).

Total estimated discards for 2010 were $37,548 \mathrm{mt}$ (see table below). Discards increased by $6.7 \%$ over the 2009 estimates. Some of the increase may have occurred due to the lower skate wing possession limit, particularly from September 3 to December 31, 2010 when the possession limit was 500 lbs . Changes in the estimated discards may also have been mitigated by reduced landings and effort by multispecies (groundfish) sector vessels.

Discard estimates from the Data Poor Stocks Working Group (DPWS) were updated and errors in the tables corrected. The ratio-estimator used in this assessment is based on the methodology described in Rago et al. (2005) and updated in Wigley et al 2007. It relies on a $\mathrm{d} / \mathrm{k}$ ratio where the kept component is defined as the total landings of all species within a "fishery". A fishery is defined as a homogeneous group of vessels with respect to gear type (longline, otter trawl, shrimp trawl, sink gill net, and scallop dredge), quarter (months 1-4, 5-6, 7-8, 9-12), and area fished (GOM, GB, SNE, MA). Mesh size was not used to split out otter trawl trips or sink gill net trips. All trips were included if they occurred within this stratification regardless of whether or not they caught skates.

The discard ratio for skates in stratum $h$ is the sum of discard weight over all trips divided by sum of kept weights over all trips:

$$
\begin{equation*}
\hat{R}_{h}=\frac{\sum_{i=1}^{n_{h}} d_{i h}}{\sum_{i=1}^{n_{h}} k_{i h}} \tag{1}
\end{equation*}
$$

where $\mathrm{d}_{\mathrm{ih}}$ is the discards for skates within trip i in stratum h and $\mathrm{k}_{\mathrm{ih}}$ is the kept component of the catch for all species. $\mathrm{R}_{\mathrm{h}}$ is the discard rate in stratum h . The stratum weighted discard to kept ratio is obtained by weighted sum of discard ratios over all strata:

$$
\begin{equation*}
\hat{R}=\sum_{h=1}^{H}\left(\frac{N_{h}}{\sum_{h=1}^{H} N_{h}}\right) \hat{R}_{h} \tag{2}
\end{equation*}
$$

The total discard within a strata is simply the product of the estimate discard ratio R and the total landings for the fishery defined as stratum h, i.e., $D_{h}=R_{h} K_{h}$. The total landings were updated to include landings of all species sold over-the-side as bait.

Missing cells were imputed using averages of existing cells. If information existed in the same area fished, the annual average discard ratio was applied in the missing cells. If the information was missing in the area fished, but available in the region (i.e. SNE and MA or GOM and GBK), then the annual average for that region was applied. There were some cases for the longline fishery in which the entire year was averaged for all areas or for a span of 12 years (1993-2004).

To hindcast the discard estimates back to 1964, a three-year average (the earliest three years of data) of the discards of skates/landings of all species was used. Estimated discards by fishery, region and half year for 1964-2010 are summarized in Table 50 to Error! Reference source not found..

In 2010, Amendment 16 to the Northeast Multispecies (Groundfish) Management Plan required an increase in observer coverage to monitor discards of groundfish. This was done with At-Sea-Monitors (ASM), whose responsibilities were slightly different than for regular observers (OB). A comparison was made between the discard rates of these ASM trips and OB trips. Given that most of the rates are similar, using these data should not bias the discard estimates. A comparison was also made between these groundfish trips, and non-groundfish trips using the same gear in the same time period and region. These were also similar enough to be combined in a single analysis of skate discards, with the larger differences between the two sampling programs that appear to result from low sample sizes for non-groundfish trips.

A final comparison for 2010 was between "otter" trawl, the "Ruhle" trawl and the "haddock separator" trawl to see if these three gear types could be combined. The ratios of the three gears are different. However, it appears that not all records in the database have the correct gear type, given that the number of trips observed is almost equal to the number of trips in the dealer database for the Ruhle and haddock separator trawls. Therefore, for estimating skate discards the Skate PDT decided to include the Ruhle and haddock separator trawls in the otter trawl category at this time.

Estimated total skate discards (dead and surviving) by gear type, half year, and region are summarized in the tables below. For the Gulf of Maine/Georges Bank region (Table 50), discards mainly arise from fishing by otter trawl vessels, although an appreciable amount are also discarded by scallop dredge vessels, presumably fishing on the Northern Edge of Georges Bank. Total discards peaked at 64,082 mt in the first half year during 1981, fell to $12,380 \mathrm{mt}$ in 1995, and rose again to $27,143 \mathrm{mt}$ in 2004. Estimated discards in 2010 were $18,328 \mathrm{mt}$.

In the Southern New England/Mid-Atlantic region, skate discards are more evenly split between vessels using otter trawls and scallop dredges, in both the first and second half years (Table 51). And somewhat more discards occur from vessels using sink gill nets than occur in the Gulf of Maine/Georges Bank region, most likely from differences in the amount of fishing effort. Total skate discards peaked at 73,886 mt in 1994, declined to $10,252 \mathrm{mt}$ in 2001, increased again to $27,200 \mathrm{mt}$ in 2003. Since 2003, total skate discards ranged between 13,500 and $19,400 \mathrm{mt}$.

Table 50. Estimated discards (mt) of skates (all species) by gear type taken in the Gulf of Maine-Georges Bank region, 1964-2010.

The discard mortality rates of skates captured by commercial fishing gear remains one of the biggest unknowns in the skate fisheries biology. A review of the primary literature reveals very little information on discard mortality of skate species of the northwest Atlantic or elsewhere. Acute mortality of several ray and skate species in an Australian prawn fishery was estimated at $56 \%$, with highest mortality in smaller individuals and male specimens (Stobutzki et al. 2002). In a squid trawl fishery off the Falkland Islands, the acute mortality of several ray species was estimated at about $40 \%$ (Laptikhovsky 2004). Benoit (2006) hypothesized that winter skate acute discard mortality is at least $50 \%$ based on observations aboard trawl survey vessels in Canada. Based on this limited information, the Skate PDT and SSC have set all catch limits and associated targets using a $50 \%$ discard mortality assumption.

Delayed mortality resulting from injury, disease, or increased predation risk has not yet been investigated in any skate or ray species. Mortality is likely influenced by a suite of factors, including species, size, sex, gear, handling time and method, and environmental conditions. Research is currently under way to empirically assess acute and delayed discard mortality in members of the NE skate complex.

During the development of 2012-2013 ABC specifications, the Skate PDT was presented with new research data collected by Dr. James Sulikowski and Dr. John Mandelman showing that post capture mortality of discarded skates on commercial length tows by vessels using standard otter trawls was much lower than had been assumed ${ }^{3}$. These data included mortality that occurred during capture and on deck processing, as well as post release mortality of skates held in underwater cages for ??? hours. For data collected so far, the average discard mortality rate was 0.20 for little skate and 0.12 for winter skate. At this time, data were insufficient to estimate discard mortality for other skates. The Skate PDT recommended that the Council use these mortality rates only for little and winter skate discard estimates captured in trawls. Thus the average discard mortality rate applied from year to year varies from the proportion of little and winter skates discarded by vessels using trawls.

The table below shows the trends in reported landings, total discards, and catch. Whichever discard mortality assumption is used, the trend in discards is about the same, increasing to a peak in the 1980s and early 1990s, declining through 1999-2001, increasing in the mid to late 2000s, and then near current levels since 2008. Discards before 1987 were more than $90 \%$ of total catch, but declined as landings began increasing, settling in the $40-60 \%$ range since 1999 (or 30 to $56 \%$ range since 1996 if a variable mortality rate is applied).

Assuming a 50\% discard mortality rate, dead discards increased about 1,000 mt from 2008-2009 levels to $18,774 \mathrm{mt}$, or $56 \%$ of total catch. Assuming a variable discard mortality rate based on recent research data, dead discards increased by nearly $3,000 \mathrm{mt}$ over 2009 levels to $12,374 \mathrm{mt}$, or $46 \%$ of total catch. The higher amount with the variable mortality rate reflects a greater proportion of skates estimated to be barndoor skate and a lower proportion of discard estimates on vessels using trawls.

[^2]Table 52. Skate catch and discard mortality.

| Year | Landings (thousand $\mathrm{mt})$ | Total discards (mt) | Dead discards |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | 50\% mortality | Discard rate | Variable mortality | Discard rate |

More recently and until 2010, PPI-adjusted prices for skate wings have risen (Figure 19) and landings have risen, partially as a result of the higher prices but also because vessels with DAS allocations have been subject to greater groundfish fishing restrictions. Generally, the prices paid for skate wings has been higher than those paid for whole skates (presumably product quality is better for a food market) and since 2004, prices have been above $\$ 0.17$ per pound. 4 Average skate wing prices in 2007 rose to nearly $\$ 0.21$ per pound and the 2007 skate wing landings were the 2nd highest on record. Quantities of skate wing landings and prices in 2008 and 2009 were nearly the same as in 2007. But in 2010, the quantity of skate wings declined, but inflation adjusted prices increased to near $\$ 0.21$ per pound, from $\$ 0.18$ to $\$ 0.19$ per pound in 2008-2009. And although there were seasonal price spikes related to short-term supply and changes in skate possession limits, the ex-vessel price was not very responsive to decreases in supply. Most of the skate wing landings are sent to foreign markets where the US product competes with other sources and substitute goods. With respect to skate wing prices, the US may be more of a price-taker for a foreign market whose prices is determined by other seafood supply.

PPI-adjusted prices for whole skates, most of which are landed to supply bait to the lobster fishery, have been relatively stable, except for 1995, 2001, and 2002. Except for three years5, whole skate prices have been generally less than $\$ 0.15$ per pound and annual landings in recent years have been around 10-15 million lbs. Including transfers at sea (for all years since 1994), skate bait landings in 2010 increase to a record 16.3 million pounds. Inflation adjusted prices however was the second highest on record, nearly $\$ 0.23$ per pound. And unlike previous years, the price per whole pound of skates was actually higher for skates destined for the bait market than for skates destined for the wing market, whereas the ratio since 2004 has been about 2:1 in favor of wing prices.

4 Prices for skate wings are actually higher by a factor of 2.27 , but these wing prices have been converted to a whole-weight equivalent to be on the same metric as prices for whole skate landings. 5 The higher prices in 1995 and 1996 may have been influenced by mis-reported (or erroneously recorded) landings of skate wings.

Figure 19. GDP deflator adjusted annual prices for skate wing and bait landings compared to quantity landed (whole weight).

### 7.5.4.3 Price Models

See Section Error! Reference source not found. which analyzes the effects of Amendment 3 alternatives and updates skate price models to estimate producer and consumer surplus.

### 7.5.4.4 Revenues from Skate Landings

Fishermen in the northeast region earned $\$ 3.178$ million from skate landings in 1999. Skate wings returned $\$ 2.461$ million, and revenues in the dealer "unclassified" market category - nearly all skate bait - were $\$ 0.717$ million. Dockside skate revenues contributed less than 0.3 percent to total fisheries revenues in the northeast region in 1999.

Revenues from skate landings are reported by state in Figure 20. Rhode Island was the leading skate bait state where fishermen grossed $\$ 571$ thousand for skate bait, more than all other states combined.
Fishermen from Connecticut and New Jersey received an order of magnitude less revenue from skate bait landings - \$59 thousand and \$50 thousand, respectively. Skate bait revenues were less than $\$ 8$ thousand in all other states. In contrast, Massachusetts lead all states in skate wings dockside revenues with more than $\$ 1.8$ million, followed distantly by RI (\$196 thousand), NJ (\$187 thousand), NY (\$129 thousand), and ME (\$105 thousand) (Figure 20). Skate wings revenues were less than $\$ 25$ thousand in all other states.

[^0]:    ${ }^{1}$ Skate landings reported as wing landings are converted using an accepted ratio of 2.27.

[^1]:    ${ }^{2}$ Amendment 3 reduced the possession limit for gillnet vessels on a Category B DAS from 20,000 lbs. to 220 lbs . of skate wings.

[^2]:    ${ }^{3}$ Before Amendment 3, the Council used a working range of skate discard mortality between 25 and $50 \%$. But for Amendment 3, the Council had to chose a value to set Total Allowable Landings limits and to monitor the amount of dead discards. Based on published literature, mainly for other skates in other countries, the Council's SSC decided to assume a $50 \%$ mortality rate.
